

Japanese position to the proposals from TU-G and TU Wien

9th HDH Informal meeting, 21-23 March, 2012

JASIC

Japanese position to the proposals by TU Wien and TU Graz

◆The proposal “Extended HILS” by TU Wien regarding the measures for COLD TEST

We do not think the proposal is appropriate for certification because of the expected huge investment for the facilities, complexity of the system and such. It is possible to modify the conventional Japanese HILS to include the water temperature table into the model in order to adjust to COLD TEST.

◆The proposal by TU Graz “WHDHC” method

The proposal is based on the idea of WHTC cycle for conventional vehicles and partly reasonable, however, it does not require the concept of vehicle-base, so it does not properly reflect the difference of specification of each vehicle.

Furthermore, the emission results of this method do not align with those of WHTC, the test method for conventional vehicles.

◆Considering the above-mentioned issues, the Japanese proposal are based on these concepts;

1. Consideration for the COLD START
2. Equivalent to WHTC while the motor is not operating
3. The influence due to the difference of HEV system is properly reflected.
4. Based on the Japanese Open Source Model

--Outline of Japanese Proposal--

WHVC is the basic cycle. Based on the Japanese open source model, obtain the operating ratio of engine to the system in chronological order by HILS simulation. Then the ratio is multiplied to the WHTC base load factor to normalize the pattern, and use the normalized pattern to develop the engine driving pattern converted to WHTC. The emission is measured on HEV engine as unit.

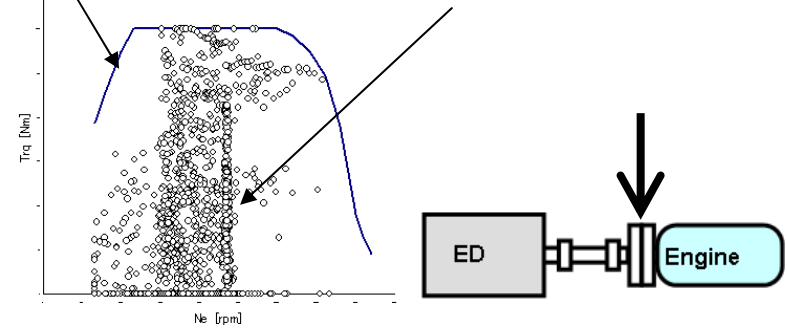

Comparison of WHTC, Japanese HILS and proposals

	WHTC (for Conv. Diesel)	Current Japanese HILS	Japanese Proposal (HEV ratio)	TU GRAZ Proposal (WHDHC)	TU Wien Proposal (Extended HILS)
Outline	Emission test is done by the RPM/torque pattern, distinctly obtained by the engine	HEV engine RPM/torque pattern is obtained by cycle (defined only by vehicle speed) simulated by HILS.	First obtain the HEV ratio by HILS using the vehicle speed of WHVC, then multiply the ratio and WHTC torque to obtain modified engine RPM/torque pattern.	Obtain HEV engine RPM/torque pattern by HILS simulation using the cycle developed from combination of WHTC power rate and WHVC vehicle speed.	The current Japanese HILS engine model is replaced to the actual engine. Method to measure the actual emission while simulating.
Necessity of concept of vehicle	NO	YES	YES	NO	YES
Provisions for negative torque	NO	Possible to reflect the effect of HEV system	<=	Defined distinctly (impossible to reflect the effect by differences of vehicle specification)	Possible to reflect the effect of HEV system
Cold test	Possible with real engine condition	Possible with real engine condition. Include the water temperature table into the model to solve the effect of HEV control	<=	<=	Possible with real engine condition
E/D	Current facilities are sufficient	<=	<=	<=	Need to modify the facility
Alignment with WHTC	—	NO: simulation on WHTC is impossible	YES: WHTC test as HEV engine is possible	NO: the test points are different from those of WHTC	NO: Simulation on WHTC is impossible
Concerns	—	Impossible to align with WHTC	WHVC load rate is not considered, but possible to modify by adding gradient condition.	Impossible to reflect the effect of HEV system b/c concept of vehicle is not considered. Impossible to align with WHTC.	Huge investments required for facilities Impossible to align with WHTC
