

Economic Commission for Europe

Committee on Sustainable Energy

Expert Group on Resource Classification

Sixth session

Geneva, 28 April – 1 May 2015

Item 11 of the provisional agenda

Application of UNFC-2009 to nuclear fuel resources

Case Studies – Application of UNFC-2009 to nuclear fuel resources

Prepared by the Expert Group on Resource Classification Task Force on Application of UNFC-2009 to Nuclear Fuel Resources

I. Introduction

1. The United Nations Framework Classification for Fossil Energy and Mineral Reserves and Resources 2009 (UNFC-2009) [1] is now fully applicable to uranium and thorium resources. This marks an important step in the development of UNFC-2009. The Bridging Document between the “Red Book” (the Uranium Classification of the Organisation of Economic Co-operation and Development Nuclear Energy Agency (NEA) and the International Atomic Energy Agency (IAEA)) was endorsed by UNECE member States on 20 November during the twenty-third session of the UNECE Committee on Sustainable Energy held in Geneva, 19-21 November 2014.

2. Bridging documents explain the relationship between UNFC-2009 and another classification system that has been agreed by the UNECE Expert Group on Resource Classification as an aligned system. They incorporate instructions and guidelines on how to classify estimates generated by application of that aligned system using the numerical codes of UNFC-2009.

3. Two international systems are used for classification and reporting of uranium and thorium deposits, the “Red Book” [2] and the Committee for Mineral Reserves International Reporting Standards (CRIRSCO) Template for solid minerals [3]. UNFC-2009, unlike other systems, covers the total resource base, including quantities that are not currently economic and the ‘unrecoverable’ part of the deposits. Exploration Results, Mineral Resources and Mineral Reserves for uranium and thorium deposits prepared under the CRIRSCO family of aligned codes and standards, can now be mapped to UNFC-2009 by applying the Bridging Document that already exists between the CRIRSCO Template and UNFC-2009. Understanding the total resource base is important for Governments in managing their national resources.

II. Application of UNFC-2009 to Uranium and Thorium Resources - Case studies

4. The eight case studies (A – H) that follow were prepared with the technical input of Mr. Harikrishnan Tulsidas of the International Atomic Energy Agency (IAEA) and Mr. Bradley Van Gosen of the United States Geological Survey (USGS). These example case studies from Argentina, Brazil, China, India, Malawi, Niger and the United States of America demonstrate that estimated quantities of uranium and thorium resources can be transparently transferred to UNFC-2009.

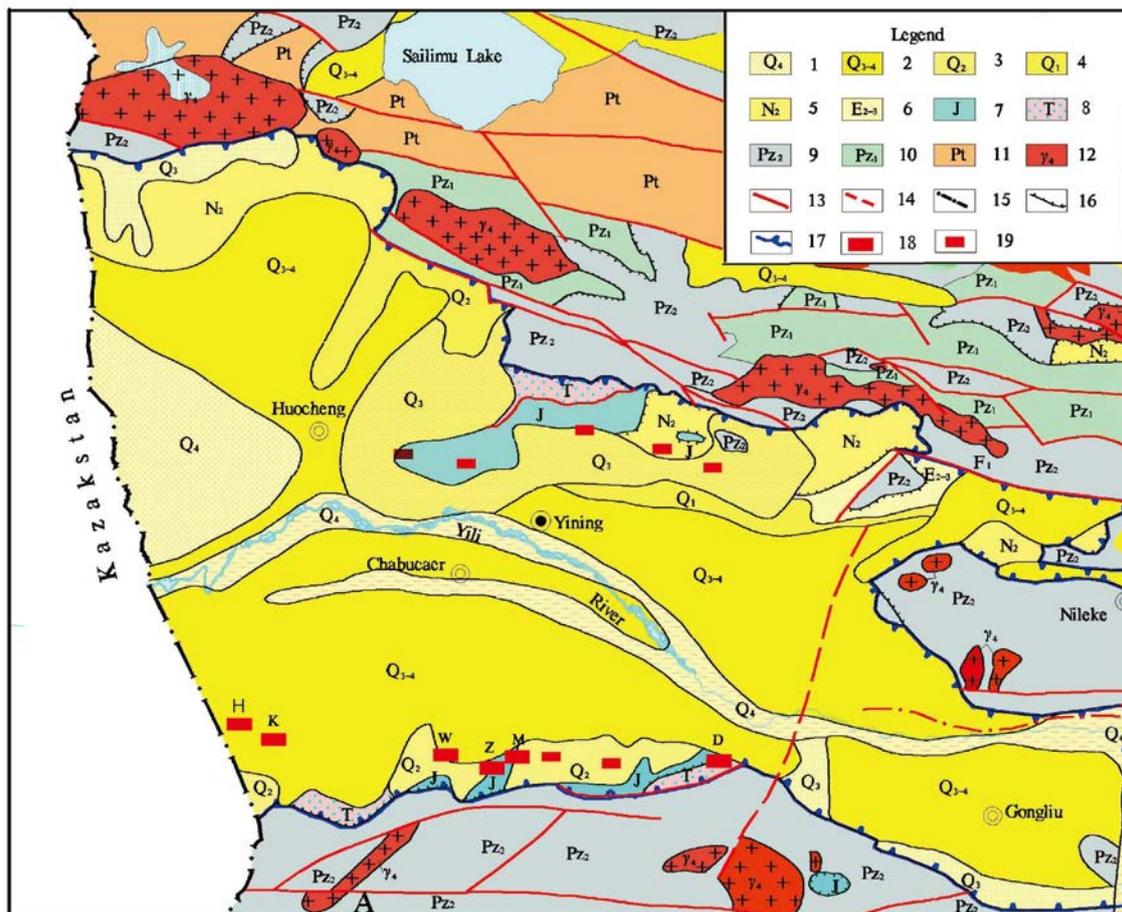

A. Case Study - Uranium Exploration and Mining in the Yili Basin, China

Prepared by Mr. Li Shengxiang and Mr. Yu Hengxu of the China National Nuclear Corporation (CNNC).

5. This case study provides considerations related to the application of UNFC-2009 to estimates of uranium resources in the Yili Basin, North West China. The uranium resources of this basin were originally classified according to the China Mineral Reserves and Resources Classification System (CMRRCS) and this case study demonstrates that the quantities may be transparently transferred to UNFC-2009. In this context, consideration may now be given to the possible development of a Bridging Document between the CMRRCS and UNFC-2009 classification systems.

6. The Yili Basin, situated in the western part of the Tianshan Tectonic Belt, North West China, is a Meso-Cenozoic intermountain basin developed on the basement of an old Precambrian block (Figure 1). The coordinates of the centre of the Yili Basin are E81°05, N43°50.

Figure 1. Geological map of the Yili Basin

Legend: 1-Holocene; 2-Upper Pleistocene-Holocene; 3-Middle Pleistocene; 4-Lower Pleistocene; 5-Pliocene; 6-Eocene-Oligocene; 7-Jurassic; 8-Triassic; 9-Upper Paleozoic; 10-Lower Paleozoic; 11-Proterozoic; 12-Hercynian granite; 13-fault; 14-inferred fault; 15-buried fault; 16-unconformity; 17-boundary of the basin; 18-U Deposit; 19-U occurrence; K-Kujiertai Deposit; W-Wukuerqi Deposit; Z-Zhajistan Deposit; M-Mengqiguer Deposit; D-Daladi Deposit; H-Honghaigou Deposit.

7. The uranium mineralization is mainly hosted in the coal-bearing clastic rocks of the Shuixigou Group (J1-2sh), the Lower-Middle Jurassic (Figure 1). The ore-hosting Shuixigou Group (J1-2sh) can be further divided into three formations, namely, Badaowan Formation (J1b), Sangonghe Formation (J1s) and Xishanyao Formation (J2x) [4] [5].

8. Uranium prospecting work began in this region in the early 1950s. During the 1950s and 1960s, the prospecting focused on coal-type uranium resources; two coal-type deposits – the Daladi Deposit and the Mengqiguer Deposit – were discovered during that time. After being suspended for about 20 years, prospecting work restarted in the early 1990s and focused on in-situ leach (ISL) amenable sandstone-type uranium deposits in the southern margin of Yili Basin. Following 25 years of geological exploration, five in-situ leachable sandstone-type uranium deposits – the Mengqiguer, Zhajistan, Wukuerqi, Kujiertai and Honghaigou deposits – have been delineated, with the total uranium resources amenable to ISL extraction estimated at over 30,000 tU (metric tons of uranium).

9. Uranium production and trial production activities using the ISL method are currently ongoing in the Mengqiguer, Zhajistan, Wukuerqi and Kujiertai Deposits, forming the largest uranium production centre in China. The total production capacity of the four deposits is around 400 tU per annum, and will expand to 500 tU per annum in the near future. Exploration work continues in the existing deposit extensions and their adjoining areas.

Classification of Uranium Resources of Yili Basin with the current China Categorization System

10. The current China Mineral Reserves and Resources Classification System (CMRRCS) for solid minerals was established in 1999 [6] [7]. It was formulated on the basis of the principles of the United Nations Framework Classification for Reserves/Resources – Solid Fuels and Mineral Commodities of 1997 (UNFC-1997). Both these systems use E, F, G axes (see Table 1). As shown in Table 1, CMRRCS has 16 categories.

Table 1.

China Mineral Reserves and Resources Classification System (CMRRCS) for solid minerals

<i>Economic Viability</i>	<i>Geological Study</i>			
	<i>Identified mineral resources</i>			<i>Potential mineral resources</i>
	<i>Measured</i>	<i>Indicated</i>	<i>Inferred</i>	<i>Prognostic</i>
Economic	Mineable Reserve (111)			
	Basic Reserve (11b)			
	Pre-mineable Reserve (121)	Pre-minable Reserve (122)		
	Basic Reserve (12b)	Basic Reserve (122b)		
Marginal Economic	Basic Reserve (2M11)			
	Basic Reserve (2M21)	Basic Reserve (2M22)		
Sub-Marginal Economic	Resource (2S11)			
	Resource (2S21)	Resource (2S22)		
Intrinsically Economic	Resource (331)	Resource (332)	Resource (333)	Resource (334)

Note: (i) the first number represents economic viability, where 1 = economic, 2M = Marginal Economic, 2S = Sub-Marginal Economic, 3 = Intrinsically Economic. (ii) The second number represents status of project feasibility study, where 1 = feasibility study, 2 = pre-feasibility study, 3 = Scoping study. (iii) The third number represents geological study, where 1 = measured, 2 = indicated, 3 = inferred, 4 = prognostic. (iv) b = mineable reserve with no consideration of mining losses.

11. The mapping of CMRRCS to UNFC-2009 is shown in Table 2.

Table 2.
Mapping of CMRRCS to UNFC-2009 Categories

No		CMRRCS			UNFC-2009		
		E	F	G	E	F	G
1	Economic Measured Minable Reserve	1	1	1	1	1	1
2	Economic Measured Basic Reserve	1	1	1b	1	1	1
3	Economic Measured Pre-minable Reserve	1	2	1	1	1.2, 1.3	1
4	Economic Measured Basic Reserve	1	2	1b	1	1.2; 1.3	1
5	Economic Indicated Pre-minable Reserve	1	2	2	1	1.2; 1.3	2
6	Economic Indicated Basic Reserve	1	2	2b	1	1.2; 1.3	2
7	Marginal Economic Measured Basic Reserve	2M	1	1	2	2.1	1
8	Marginal Economic Measured Basic Reserve	2M	2	1	2	2.1	1
9	Marginal Economic Indicated Basic Reserve	2M	2	2	2	2.1	2
10	Sub-Marginal Economic Measured Basic Reserve	2S	1	1	2	2.2	1
11	Sub-Marginal Economic Measured Basic Reserve	2S	2	1	2	2.2	1
12	Sub-Marginal Economic Indicated Basic Reserve	2S	2	2	2	2.2	2
13	Intrinsically Economic Measured Resource	3	3	1	2; 3.2; 3.3	2.1; 2.2; 2.3	1
14	Intrinsically Economic Indicated Resource	3	3	2	2; 3.2; 3.3	2.1; 2.2; 2.3	2
15	Intrinsically Economic Inferred Resource	3	3	3	2; 3.2; 3.3	2.1; 2.2; 2.3	3
16	Intrinsically Economic Prognostic Resource	3	3	4	3.2	3	4

12. Classification of the uranium resources of the Yili Basin was undertaken according to the mapping of CMRRCS to UNFC-2009 that is shown in Table 2 and results are shown in Table 3.

Table 3.
Classification of the Uranium Resources of the Yili Basin

Deposits	UNFC-2009 Class	UNFC-2009 Sub-Class	UNFC-2009 Categories	CMRRCS
Mengqiguer-2 (sandstone type)	Commercial Projects	On production	E1.1F1.1G2, E1.1F1.1G3	122b,332 ^a 333
Mengqiguer-1 (coal type)	Non Commercial Projects	Development not viable	E3.3F2.3G2, E3.3F2.3G3	332 333
Kujiertai	Commercial Projects	On production	E1.1F1.1G1, E1.1F1.1G2, E1.1F1.1G3	121b, 122b,332 ^a 333
Zhajistan	Commercial Projects	On production	E1.1F1.1G1, E1.1F1.1G2, E1.1F1.1G3	121b, 122b,33 ^a 333
Wukuerqi	Commercial Projects	On production	E1.1F1.1G2, E1.1F1.1G3	122b,33 ^a 333
Daladi	Non Commercial Projects	Development not viable	E3.3F2.3G2, E3.3F2.3G3	332 333
Honghaigou	Potentially Commercial Projects	Development Pending	E2F2.1G3	333

^a Because detailed feasibility studies (DFS) or pre-feasibility studies (PFS) for the development of the deposit were done in the central area of the deposit and did not cover the extension area, the resources of the extension part of the deposit have not been converted into 122b from 332 in the existing CMRRCS report.

Application of UNFC-2009 to the uranium deposits of the Yili Basin

Mengqiguer Deposit

13. The Mengqiguer Deposit is the largest uranium deposit in the Yili Basin. The deposit accounts for about 45 per cent of the total uranium resources of the Basin. The uranium ore bodies are mostly hosted in the Xishanyao Formation and the Sangonghe Formation.

14. The uranium mineralization discovered during the 1950s and 1960s was found to be hosted in coal beds (named as Mengqiguer-1). The quantity is small. Since this material is difficult to process, this kind of coal type uranium mineralization is considered as “Development not viable” with categories E3.3 F2.3 G2, E3.3 F2.3 G3 (Table 3).

15. The uranium mineralization discovered after 2000 was found in permeable sandstone layers, which allows the uranium to be extracted with the ISL method (named as Mengqiguer-2). The ISL-amenable uranium resources of the deposit account for about 43 per cent of the total resources of the basin. Since the on-going trial uranium production with the ISL method in the deposit shows positive commercial results, this type of sandstone type uranium mineralization is considered as “On production” with categories E1.1 F1.1 G2, E1.1 F1.1 G3 (Table 3). More geological work needs to be carried to increase the geological confidence of these resources.

Kujiertai Deposit

16. The Kujiertai Deposit is the second largest uranium deposit, the first ISL-mining uranium deposit in the Yili Basin, and also the first commercial ISL uranium production centre in China. The deposit accounts for about 23 per cent of total uranium resources of the basin. It was discovered in early 1990s and the uranium ore bodies are mostly hosted in the permeable sandstone layers of the Xishanyao Formation and the Badaowan Formation. The uranium production of the deposit began in middle of 1990s using the ISL method. The uranium mineralization is considered as “On production” with categories E1.1 F1.1 G1, E1.1 F1.1 G2, E1.1 F1.1 G3.

Zhajistan Deposit

17. The uranium ore bodies of the Zhajistan Deposit are mostly hosted in the Xishanyao Formation and the Sangonghe Formation with the uranium resources constituting about 10 per cent of the total resources of the basin. The uranium mineralization is hosted in permeable sandstone layers and is being mined with the ISL method, in which case the uranium resources are considered as “On production” with categories E1.1F1.1G1, E1.1F1.1G2, E1.1F1.1G3.

Wukuerqi Deposit

18. The uranium ore bodies of the Wukuerqi Deposit are mostly hosted in the Xishanyao Formation and the Sangonghe Formation with the uranium resources constituting about 7 per cent of the total uranium resources of the basin. The uranium mineralization is hosted in permeable sandstone layers and is being mined with the ISL method, so the uranium resources are considered as “On production” with categories E1.1 F1.1 G2, E1.1 F1.1 G3. However, more geological work needs to be carried out to increase its geologic confidence.

Daladi Deposit

19. The Daladi Deposit is the earliest discovered uranium deposit in the Yili Basin. The uranium ore bodies are mostly hosted in the Xishanyao Formation and the Sangonghe Formation with the uranium resources being less than 3 per cent of the total resources of the Basin. The uranium

mineralization is hosted in the coal beds and is difficult to process, so these uranium resources are considered as “Development not viable” with categories E3.3F2.3G2, E3.3F2.3G3.

Honghaigou Deposit

20. The Honghaigou Deposit is a new deposit that was discovered in recent years, and the exploration and the pre-feasibility studies are still ongoing in the deposit. The uranium ore bodies are mostly hosted in the Upper Jurassic and the Xishanyao Formation with the uranium resources constituting about 12 per cent of the total resources of the basin. The uranium mineralization is classified into “333” in the current CMRRCS. However, considering that the uranium mineralization is hosted in permeable sandstone with similar mineralization characteristics to that of the Kujiertai Deposit, and that the deposit can be mined using the ISL method, the uranium resources are considered as “Development Pending” with categories E2 F2.1 G3.

Conclusions

21. From this case study on the application of UNFC-2009 to the uranium resources in the Yili Basin, it can be concluded that if a comprehensive consideration of the project socio-economic viability and project status and feasibility is undertaken, the mapping of CMRRCS Classes to UNFC-2009 Classes will be relatively easy and straight forward. UNFC-2009, in particular with its Sub-classes, is a very useful uranium resources categorization tool because it can provide an overall picture of a uranium project. Additionally, UNFC-2009 can express the project more comprehensively and more precisely than UNFC-1997 and CMRRCS, especially in relation to project status and feasibility.

B. Case Study – Application of UNFC-2009 to the uranium resources of the Azelik Deposit, Niger

Prepared by Mr. Li Shengxiang of the China National Nuclear Corporation (CNNC).

22. The Azelik Uranium Deposit is located in the north-western region of Niger. It is a sandstone-type uranium deposit hosted in the Cretaceous strata of the Tim Mersoï Basin. Based on the geological survey, core observation and documentation, the uranium mineralization is related to hydrothermal fluid flow [8].

23. In 2006, the China National Nuclear Corporation acquired the project and conducted an estimation of the uranium resources through application of the China Mineral Reserves and Resources Classification System (CMRRCS). The resource estimation was carried out prior to the Definitive Feasibility Study (DFS) being undertaken. In 2008, China National Nuclear Corporation completed the DFS for the project, following which construction of the mine began.

24. The aggregate uranium resources estimation according to CMRRCS before carrying out the DSF was 13,692 metric tons of uranium (tU). After completing the DFS, the aggregate resources according to CMRRCS were estimated to be 12,763 tU (Table 4).

Table 4. Estimated uranium resources of the Azelik Deposit, calculated before and after the Definitive Feasibility Study (DFS).

<i>Deposit</i>	<i>Type</i>	<i>Resources before DFS</i>			<i>Resources after DFS</i>			
		CMRRCs category	CRIRSCO ^a Template	tU	CMRRCs category	CRIRSCO Template	NEA/IAEA “Red Book” Classification	tU
Azelik	Sandstone	331	Measured Resources	1821	111	Proven Reserves	RAR (<USD 130/KgU)	1821
		332	Indicated Resources	8788	122 ^b	Probable Reserves	RAR (<USD 130/KgU)	8664
		333	Inferred Resources	3083	2M22 ^b	Inferred Resources	IR (<USD 130/KgU)	2278
Total				13692				12763

^a Committee for Mineral Reserves International Reporting Standards (CRIRSCO).

^b In view that the geological confidence was not high enough due to insufficient infill drilling during the DFS, China National Nuclear Corporation transferred the former 332 into 122 and 333 into 2M22 by excluding some high-cost resources. The feasibility study level was lowered to pre-feasibility study results rather than moving the resources into proven reserves.

The Case Study

25. The Estimated uranium resources of the Azelik deposit after the DFS were classified according to the United Nations Framework Classification for Fossil Energy and Mineral Reserves and Resources 2009 (UNFC-2009). The mapping to the Organisation of Economic Co-operation and Development (OECD) Nuclear Energy Agency (NEA)/International Atomic Energy Agency (IAEA) resource reporting scheme and CMRRCs is shown in Table 5. This is aided by the mapping scheme described for CMRRCs and UNFC-2009.

Table 5.

Estimated uranium quantities in the Azelik Project classified under UNFC-2009 (as at December 2010)

Project	<i>UNFC-2009</i>				<i>NEA/IAEA “Red Book” Classification</i>			<i>CMRRCs</i>	
	Class	Sub-class	Categories	(tU)	Production Centre Status	Classification	(tU)	Class	(tU)
Azelik	Commercial Project	On Production	E1.1F1.1G1	1821	Existing	RAR ^a <\$130/Kg	10,485	111	1821
			E1.1F1.1G2	8664				122	8664
Azelik	Potentially Commercial Project	Development Pending	E2F2.1G3	2278	Prospective	IR ^b <\$130/Kg	2,278	2M22	2278
Total				12763			12763		12763

^a Reasonably Assured Resources.

^b Inferred Resources.

Conclusions

26. In this Case Study the cost categories as used in the NEA/IAEA “Red Book” classification are also used for each of the Classes. This example shows that mapping of the existing CMRRCs categories and quantities to the NEA/IAEA “Red Book” Classification and UNFC-2009 can be completed in a straightforward manner.

27. Even though the mapping of UNFC-2009 to CMRRCS has been defined only at a class level, the use of sub-classes – as in this case study – can add further information about the project and application of the UNFC-2009 principles and generic specifications. Thus, the full granularity of UNFC-2009 can be applied to derive maximum benefits.

Observations, Conclusions and Recommendations

28. The work undertaken in preparing case studies A (Yili Basin, China) and B (Azelik Uranium Deposit, Niger) usefully demonstrates that quantities can be transparently transferred to UNFC-2009 from CMRRCS.

29. The Yili Basin case study highlighted issues related to the use of UNFC-2009 for In-situ Leaching (ISL). It was noted that there are examples in Australia, Kazakhstan and USA where the CRIRSCO Template is applied to ISL projects. In some cases this can generate debate due to the fact that the recovery factor is usually a major uncertainty. Application of UNFC-2009 can facilitate representation of this uncertainty through use of the G-axis categories.

30. The Azelik Uranium Deposit case study demonstrates that mapping of the existing CMRRCS categories and quantities to the NEA/IAEA “Red Book” Classification and UNFC-2009 can be carried out in a straightforward manner.

31. Even though the mapping of UNFC-2009 to CMRRCS has been defined only at a Class level, the use of Sub-classes – as in the Azelik Uranium Deposit case study – can add further information about the project and application of the UNFC-2009 principles and generic specifications. Hence, the full granularity of UNFC-2009 can be applied to derive maximum benefits.

32. The two case studies serve to confirm that there would appear to be a straightforward relationship between the CMRRCS Classes and the UNFC-2009 Classes and hence consideration may now be given to the possible development of a Bridging Document between the two systems.

C. Case Study - Application of UNFC-2009 to the uranium resources of Argentina

Prepared by Mr. Luis López, National Atomic Energy Commission, Argentina.

32. Historically, uranium resources in Argentina have been classified and reported according to the Organisation of Economic Co-operation and Development (OECD) Nuclear Energy Agency (NEA)/IAEA resource reporting scheme. This system consists of a biaxial classification that considers the degree of geological knowledge and the production costs of uranium concentrate.

33. In 2011, the National Atomic Energy Commission of Argentina (CNEA) reported about 20,000 tonnes of uranium (tU) as Identified Resources (Reasonably Assured Resources + Inferred Resources) for the production cost category <130 USD/kgU [2]. In addition, about 11,000 tU of Canadian National Instrument 43-101 [9] certified resources have been reported in recent years by public mining companies [10] [11] (Figure 2). The total uranium resources of Argentina are thus approximately 31,000 tU in the aforementioned Identified Resources category (see Table 6).

34. UNFC-2009 allows the documentation and reporting of these uranium resources of the country. UNFC-2009, in addition to providing the project maturity of resources, considers social and economic issues, including regulatory, legal and market conditions imposed by governments and markets, domestic demand, technological and industrial progress and the ever-present uncertainty.

Table 6. Uranium Identified Resources in Argentina according to the NEA/OECD – IAEA classification scheme.

<i>Deposit</i>	<i>Type</i>	<i>RAR tU</i> <i>≤ USD 130/kgU</i>	<i>IR tU</i> <i>≤ USD 130/kgU</i>
Sierra Pintada (CNEA)	Volcanic-related	3,900	6,110
Cerro Solo (CNEA)	Sandstone- hosted	4,420	4,810
Don Otto (CNEA)	Sandstone- hosted	130	300
Laguna Colorada (CNEA)	Volcanic-related	100	60
Laguna Salada (U3O8 Corporation)	Surficial	2,420	1,460
Meseta Central (UrAmerica Ltd)	Sandstone- hosted	-	7,350
Sub Total		10,970 tU	20,090 tU
Total		31,060 tU	

RAR – Reasonably Assured Resources

IR – Inferred Resources

35. For the uranium resources of different projects of CNEA and mining companies, the criteria of UNFC-2009 concerning social and economic viability (E), technical feasibility (F) and geological knowledge (G) were defined at the sub-category level and grouped into major classes considered in this classification system, as shown in Table 7 [12].

36. The identified uranium resources in Argentina are mostly located in the provinces of Chubut and Mendoza. These are areas where no metallic mineral mining projects are in operation. In addition, legislation is in place that markedly restricts uranium production, which needs to be taken into account when studying the social viability of the projects. In Chubut, projects need to wait for the Chubut provincial territory zoning provisions of Law 5001/2003, as well as the introduction of a mining regulatory framework for this jurisdiction [13]. Moreover, the operation of uranium mining and processing in Sierra Pintada will require major changes to the legislation, such as permitting of open pit mining and the use of sulphuric acid, both which are currently forbidden by Law 7722/2007 [14].

Table 7. Uranium Resources in Argentina according to UNFC-2009 – NEA/IAEA classification schemes.

<i>Project</i>	<i>UNFC Class</i>	<i>UNFC Sub-class</i>	<i>UNFC Categories</i>	<i>Resources (tU)</i>	<i>NEA/IAEA Production Centre Status</i>	<i>NEA/IAEA Classification</i>	<i>Resources (tU)</i>	<i>Total (tU)</i>

			E3.2 F2.2 G2	60				
			E3.2 F2.2 G3	300				
Laguna Colorada	Non Commercial Projects	Development not Viable	E3.3 F2.3 G1	80	Not Viable	RAR <\$130/Kg	100	160
			E3.3 F2.3 G2	20				
			E3.3 F2.3 G3	60				

37. To define the economic feasibility of CNEA's projects, uranium prices in the international market are taken as a reference, not as a determining factor, considering that the raw material has a bearing of five to seven per cent in the total cost of nuclear energy in the country. Argentina so far has not pursued the objective to obtain dividends from the sale of uranium in international markets. For domestic use uranium is imported, which has implications for security of supply.

38. In recent years, an increase in exploration efforts has led to a significant increase in uranium resources and their level of knowledge, especially in the San Jorge Basin, which extends over about 180,000 km² and hosts not only important uranium deposits, but also oil and gas resources.

39. In the Cerro Solo deposit (Chubut province), tonnage and grade estimated is expected to ensure sustained uranium production in the future. This blind deposit was discovered in 1971 and since then, exploration and evaluation drilling programs have amounted to 100,700 metres. It is located in Cretaceous fluvial sandstones and conglomerates of the Chubut Group. In this paleochannel structure, the mineralized levels are 0.5 – 6 meters wide and 50 – 130 meters deep. The identified resources are 9,230 t U at approximately 0.2 % U, included in the < USD 130/Kg U production cost category. The reported resources correspond to the two most studied mineralized bodies and the available geological knowledge indicates very good perspectives to develop new uranium resources in this mining property [15] [16] [17] [18] (Figure 3).

40. Currently, a program to complete the feasibility study of the Cerro Solo deposit is being carried out. As background, in 1997 the CNEA retained NAC International to complete a pre-feasibility study of the Cerro Solo uranium deposit, including geological model revision and ore reserves estimate, mining and milling methods and their costs, cash flow and risk analysis [19]. Also, the social-environmental baseline is being surveyed in cooperation with national universities and research councils.

41. Regarding by-products, it can be mentioned that though economic recovery of molybdenum has not been defined for the Cerro Solo deposit, the potential economic benefits of income from this process justify further research and evaluation in both the extent of molybdenum reserves and its recovery. In addition, anomalous assays of rhenium were detected in Cerro Solo, and its potential should be the subject of further research.

42. The Sierra Pintada uranium deposit (Mendoza province) belongs to the volcanic-related model, where mineralization is localized in Permian formations associated with synsedimentary acid volcanism [20] [21].

43. The level of uncertainty in the estimation of remaining resources in Sierra Pintada is medium to high, which are evaluated to be 10,010 t U recoverable at a production cost below USD 130/Kg U [22].

44. This deposit has been the focus of the most important uranium exploitation in the country, with a total production of 1,600 t U from 1975 to 1997, when the mining-milling facility was put in stand-by status for economic reasons. Therefore, feasibility has been partially demonstrated by the fact that this deposit was previously in operation, using an acid heap-leaching mining method. However, other alternatives have been considered for possible future production, including the use of alkaline leaching [23], bioleaching [24] and vat leaching [25] (Figure 4).

45. The Laguna Salada project (Chubut province) includes the Guanaco and Lago Seco areas, corresponding to a surficial uranium-vanadium deposit. Mineralization occurs within 3 metres from the surface in soft, unconsolidated gravel. Uranium Identified Resources have been evaluated at 3,880 t U at grades ranging between 55 and 72 ppm U, while vanadium Identified Resources have been evaluated at 21,330 t V at grades ranging from 308 to 330 ppm V.

46. Initial metallurgical results show uranium and vanadium grades are increased between 3 and 11 times by simple screening, followed by rapid uranium-vanadium extraction using alkaline leaching in the Guanaco area of the deposit, while acid leach is very effective in the Lago Seco area.

47. Recently, U3O8 Corp has reported a favourable Preliminary Economic Assessment (PEA) for the Laguna Salada deposit (Figure 5), based on previous NI 43-101 report, taking into consideration U-V comprehensive extraction. However, it can be considered that the PEA includes around 40% inferred resources; to the extent that follow up exploration activities can increase resources and their geological knowledge, the project could move to a UNFC-2009 class of Potentially Commercial Projects [26] [27].

48. Meseta Central project (Chubut province) is located in the vicinity of Cerro Solo and comprises the Graben, Plateau West and Plateau East deposits. Uranium mineralization is hosted by siltstones, sandstones and conglomerates of the fluvial and lacustrine origin of the Cretaceous-aged Los Adobes Formation. Mineralized layers lie between 40 and 140 meters beneath the surface, are flat-lying or very gently dipping, and are up to 15 meters in thickness [28]. The total Inferred Resources for the project are 7,350 t U at an average grade of 260 ppm U. These resources used data from two drilling campaigns comprising 178 boreholes for a total of 21,450 meters of drilling. Boreholes are mostly on a 200 by 200 meters grid. As reported by UrAmerica Ltd., about 75% of the uranium resources evaluated are placed in confined aquifers layers. Therefore, further geological and hydrological studies will be addressed to determine the amenability to in situ leaching mining. The results of these studies could play a relevant role regarding the socio-economic viability of this project (Figure 6).

49. The Don Otto (Salta province) uranium deposit is a tabular U-V subtype, occurring in the Cretaceous Yacoraite Formation of the Salta Basin; this basin covers approximately 150,000 ha, and is also known for its oil and gas potential. Don Otto was in operation from 1963 to 1981 and produced 201 t of U at 0.1%-0.2% U grade [29] [30]. When mapping to the E, F and G axes, the Don Otto deposit is classified as a "non-commercial project" where development is not clarified. However, it should be highlighted that as this deposit was previously in operation and current exploration/evaluation studies yielded very encouraging results, it could be possible in the future to move the project to a higher UNFC-2009 class. Additionally, enlargement of the mining property and resource augmentation are considered key factors to ensure the project feasibility. A comprehensive study that includes updating EIA reports, block-leaching research and development studies, feasibility of underground extraction, use of mobile ionic exchange plant, and uranium recovery from the former heaps and remediation of the site, are all factors that would aim in the same direction of increasing project viability [31] [32] (Figure 7).

50. The limited resources of Laguna Colorada (Chubut province) [16] make it difficult to envisage extraction at present, unless the characteristics of the ore will allow treatment in a plant that may in the future be located in the area of Cerro Solo (Figure 8).

51. Ultimately, the Cerro Solo project appears to be the most promising uranium project in Argentina, and with realistic assumptions of possible market conditions and obtaining social license, there are prospects for extraction in the near future.

52. The application of UNFC-2009 as a complement to the NEA/IAEA Classification contributes to both a better understanding of the availability of reliable resources in Argentina as well as how these resources can contribute to the national nuclear energy program.

D. Case Study - Application of UNFC-2009 to the thorium resources of Brazil

Prepared by Roberto Villas-Bôas, Centre for Mineral Technology, Brazil.

Summary of deposits

53. Thorium reserves within monazite were mined from beaches in Prado, south of Bahia, Brazil, by John Gordon starting in 1886. This monazite was mainly, but not only, exported to European markets, notably to Austria and Germany for the manufacture of the Auer gas lamp net bags. In fact, Brazil was the biggest player in thorium markets until 1915, when it was overtaken by India, and until 1945, when alternatively India and Brazil disputed the first rank of thorium production. In 1955, the Brazilian resources (identified domestic monazite quantities (in situ)), were roughly estimated as shown in Table 8.

Table 8. Data from Apud Othon Leonardos, in Memória SBPC • Ata da Primeira Reunião 25/04/1956 [33].

STATE	1000 t of monazite
Rio Grande do Norte	50 to 100
Bahia	35 to 50
Espírito Santo	200 to 300
Rio de Janeiro	100 to 150
Minas Gerais	50 to 130
Brazil TOTAL	435 to 730 (300 to 600 in the original)

54. By 1942, a chemical processing plant to process monazite was built by ORQUIMA S.A., an industry located in the city of São Paulo; this operation was devoted to the manufacture of rare earths oxides, becoming a major exporter to the USA. Monazite-rich sands were also mined and beneficiated at the SUPRA / SULBA plant in Buena beach, Rio de Janeiro, until 1960. From this processing an inventory of about 2,000 t of mixed thorium chlorides, known as TORTA 2, is stockpiled at the INB's (Indústrias Nucleares do Brazil) Caldas Mine in Minas Gerais.

55. It is well known that by the mid-1960s the Mountain Pass Mine in California, USA (case study F) came into full production and then dominated global rare earth element production. The Mountain Pass operation led global supply of rare earth elements until 1985, when China began their large-scale production of rare earths. By 2002, China dominated the market of rare earths oxides, while further setting thorium apart from rare earth element production. With almost no demand for thorium, this resulted in little geological exploration for thorium. However, due to a recent rebirth in research towards thorium -based nuclear reactors, thorium-containing deposits may experience some increasing demand hence necessitating a new evaluation of thorium deposits.

56. The principal thorium containing deposits and types in Brazil are listed in the IAEA – Thorium Deposits database [34]; references are provided in this database.

57. New rare earths ore deposits that might be of interest for their thorium content were recently (2013) registered and approved by the Brazilian National Department of Mineral Production (DNPM) [35].

58. Thorium resource estimates are based on limited sampling and extrapolations, thus considered as estimates at the lowest level of geological confidence. Using UNFC-2009 as a classification system, these deposits might be classed generally as 3, 3, 3, except for the Buena Mine, which previously had estimates at higher levels of confidence.

Mina Buena: Classification of the case study according to UNFC-2009

59. As a monazite mine for Rare Earth Elements (REEs), the Mina Buena, or Buena mine of INB (Figure 9), is classified as shown in Table 9; that is:

E1.2 “Extraction and sale is not economic on the basis of current market conditions and realistic assumptions of future market conditions, but is made viable through government subsidies and/or other considerations.”

F1.1 “Extraction is currently taking place.”

G1+G2 “Quantities associated with a known deposit that can be estimated with a high level of confidence” (Proven Reserves) (G1) and “with moderate level of confidence” (Probable Reserves) (G2).

Table 9. Monazite resources of the Buena Mine, São Francisco de Itabapoana, Rio de Janeiro. Source: Brazilian Minerals Yearbook, AMB, 2010 [36].

Buena Mine deposit	Quantities (metric tons)	Average Grade	CRIRSCO Classification	UNFC-2009 Categories			UNFC-2009 Class	UNFC-2009 Sub-Class
				E	F	G		
Total Monazite sands	608,690 *	0.103 % monazite [37]	Proven + Probable	1.2	1.1	1+2	Commercial Project	On Production (based on old stockpiles)
ThO ₂	31.35 based on 5% ThO ₂ analysis of the TOTAL monazite *[36]		Proven + Probable	3.3	2.3	1+2	Non-Commercial Project	Development Unclarified (foreseen IF Th reactors become a reality)

* Proven and probable monazite and ThO₂ resources based on an estimated total of 1 292 282 metric tons of monazite sands resources “in situ”, at Buena, São Francisco de Itabapoana, Estado do Rio de Janeiro.

60. On the other hand, there is no current market for thorium as a commodity. However, the large monazite resources represent a potential future source of thorium if needed or desired.

61. Mining in Buena was conducted in a very simple, logical and rational way: first, soil rich in organic matter was removed and stored for reclaiming purposes; second, overburden was then shoveled off; third, shoveling continued, which extracted the monazite-rich ores (ancient beach sands); fourth, trucks transported the ores to the physical beneficiation plant located nearby (Figure 10); fifth, concentrates and wastes were produced; and sixth, reclamation of the mined area was performed.

62. A two-step physical beneficiation process was performed, along with site reclamation:

- (a) Humphrey’s spirals concentrated the “heavy minerals” part of the “monazite sands”, producing a concentrate consisting of monazite, ilmenite, zirconite and rutile. Waste products from this operation—paleo seashore sands—were returned for the concomitant reclaiming operations.
- (b) Concentrates from step one were subject to electromagnetic, electrostatic and further gravimetric operations to produce cleaner concentrates. The overall ore recovery was 85 per cent for the heavy minerals.

- (c) Reclamation was performed concomitantly, transporting the waste materials from the concentrations steps one and two described earlier to fill the mining trenches then cover the fill with the separated and stored upper soil from operation one.

63. In fact, the Buena Mine has been working since 2011 from stockpiled ores and is currently planning for closure [38]:

STOCKPILE/YEAR (t)	2011	2012	2013
Monazite	1500	2700	600
Zirconite/Rutile	1450	1200	750
Ilmenite	10500	12000	10500

An estimate [38] of remaining stockpiles for Zirconite/Rutile, 10,000 t; Ilmenite, 50,000 t; and Monazite, 7,000 t; thus, still classified as E(1.2),F(1.1),G(1+2).

Conclusion

64. UNFC-2009 allows a better understanding of the availability of Brazilian thorium resources and reserves and certainly is a valuable tool to future planning of thorium nuclear energy uses as well as REE deposits.

Figure 9. The Buena Mine of INB – Indústrias Nucleares do Brasil – located in northeast Rio de Janeiro (21°24'36"S, 41°00'18"W). This was the only REE-producing mine in Brazil. The ore body is beach placer monazite-rich sand. The mine has been in standstill since the Chinese boom of rare earth production [39]; it reopened operations with stockpiled ore in 2011 [40].

E. Case Study - Application of UNFC-2009 to Uranium Deposits in India

Prepared by A.K. Sarangi, Uranium Corporation of India Ltd. Jaduguda, India and P.S. Parihar, Atomic Minerals Directorate for Exploration and Research, India.

Introduction

65. India's uranium exploration program started in 1948–1949 after the formation of the Indian Atomic Energy Commission. Initially, the emphasis of exploration was laid on the existing mineral belts and geologically favourable areas of the sub-continent. The maiden effort in the Singhbhum copper belt (Singhbhum Shear Zone or SSZ) became a major success story, where a uranium-bearing stretch containing over 50 anomalies was discovered in early 1950s. Since then, uranium exploration concepts and practices have undergone many changes with increased knowledge on the geology of the terrain along with global development of exploration tools.

66. A total of 12 low-grade, small to medium size uranium deposits have been established in the SSZ. Presently, seven mines and two mills are producing uranium from this province. Apart from the SSZ, potential for uranium deposits has now been recognized in other Proterozoic and Phanerozoic basins of India [41] [2]. These include:

- Umra (Metamorphite type), Rajasthan;
- Tummalapalle (Carbonate type), Andhra Pradesh;
- KPM-Wahkyn-Tyrnai-Umthongkut-Gomaghat (Sandstone type), Meghalaya;
- Bodal-Jajawal (Metamorphite type), Chhattisgarh;
- Lambapur-Peddagattu-Chitrial-Koppunuru (Unconformity type), Andhra Pradesh;
- Rohil (Metasomatite type), Rajasthan;
- Gogi (Unconformity type), Karnataka

A number of smaller deposits are also reported from other parts of India.

Uranium resources in India

67. Nearly 160,000 tU are reported contained in 40 small to medium size deposits in the country [2]. Six major uranium provinces have been identified, which are the Singhbhum Shear Zone

(Metamorphite type), Southern Cuddapah (Carbonate type), Northern Cuddapah (Unconformity type), Mahadek Basin (Sandstone type), North Delhi Fold Belt (Metasomatite type) and Bhima Basin (Unconformity type). A number of occurrences have also been established in other promising areas.

68. Of the total identified uranium resources in India, the Cuddapaha Basin (Proterozoic) in Andhra Pradesh accounts for 51%, the Singhbhum Shear zone (SSZ) (Proterozoic) in Jharkhand hosts 29%, the Mahadek Basin (Phanerozoic) in Meghalaya hosts 11%, the North Delhi fold belt (Proterozoic) in Rajasthan hosts 4%, the Bhima Basin (Proterozoic) in Karnataka hosts 2%, and the remaining uranium occurs in other Proterozoic Basins of the country. Uranium deposits of India are of low grade (less than 0.1% U).

Classification of uranium resources in India

69. Uranium resource estimation and reserve categorization in India is generally done following Indian Bureau of Mines (IBM) guidelines proposed in 1981 [42]. These guidelines are based on the concept of McKelvey System [43] and are comparable with the CRIRSCO Template. In 2003, IBM made it mandatory to report mineral resources adopting the UNFC of 1997. Currently, discussions are in progress to adopt UNFC-2009 for uniform reporting of all resources, including petroleum. However, reporting of uranium continues to be in earlier guidelines of IBM.

70. Uranium resources are also classified as per the NEA-IAEA classification scheme under the categories identified and undiscovered resources. Identified resources are normally not reported in cost categories in India.

71. With globalization of the Indian nuclear sector, there is a greater need for the Indian uranium industry to align its current system of resource/reserve estimation with global practices, reporting procedures, and associated risks. Accordingly, the uranium industry is attempting to orient its system of resource/reserve reporting procedures in line with global developments. Efforts are being made to assess different uranium exploration projects in the framework of UNFC-2009 class/subclass system. It has been appreciated that the inherent granularity in the UNFC-2009 class/subclass scheme shall help to classify the projects on the basis of their mineable status.

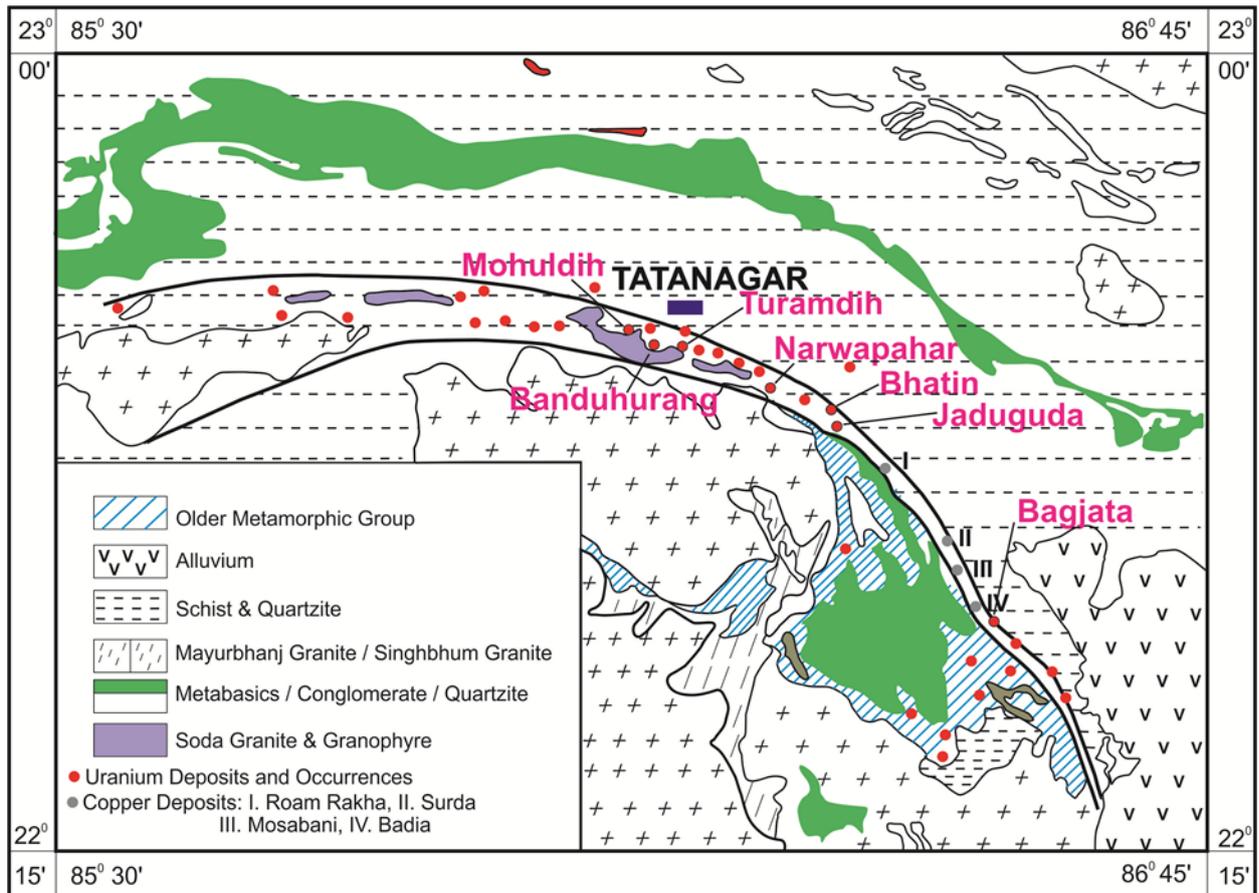

72. In India, two Government agencies—the Atomic Minerals Directorate for Exploration and Research (AMD) and the Uranium Corporation of India Ltd. (UCIL) under the Department of Atomic Energy are engaged in exploration and mining of uranium, respectively. The geological details (G axis) of almost all deposits discovered so far by the AMD have been extensively studied (G1 / G2 / G3). The technical feasibility studies (F axis) by UCIL are carried out on a case-by-case basis as more and more geological details emerge during the exploration. As the uranium is exclusively used by Government of India, the economic consideration (E axis) towards development of uranium deposits is not related to internal market-based production. Financial viability of Indian uranium deposits is to some extent related to national production scenarios reviewed time to time.

Aligning uranium deposits in the Singhbhum Shear Zone (SSZ) to the UNFC-2009 class/subclass system

73. More than 46,000 t U resources have been established in the Singhbhum Shear Zone, a major uranium province in India. All the deposits in the province are of <0.1% U grade. Presently, seven deposits are being mined.

74. Responding to the global efforts for finding a common code and terminologies for representation of mineral resources and the gradual acceptance of UNFC-2009 by various countries, an attempt has been made to place all known deposits (mines/deposits/occurrences) in the Singhbhum Shear Zone of India (Figure 11) under UNFC-2009 class and UNFC-2009 subclass categories.

Figure 11. Uranium deposits and occurrences of the Singhbhum Shear Zone, India.

75. The deposits with active mining in the Singhbhum Shear zone (Jaduguda, Bhatin, Narwapahar, Bagjata, Turamdih, Banduhurang and Mohuldih) (Figure 11) are considered as “On production” with categories E1.1, F1.1, G1, 2. These deposits account for about 57% of the total known uranium resources in the area and 15% of the total known resources of the country.

76. The resources reported around existing operating mines, such as the Banadungri-Sinidungri extensions of the Narwapahar and Jaduguda deposits, are grouped under the UNFC-2009 class of “Potentially commercial projects”, because they may emerge as production centers under changed socio-economic considerations in the foreseeable future. These deposits may be categorized as E2, F2.2, G1,2,3 (Table 10). Nearly 10% of the resources of the SSZ fall under this class.

77. Resources identified in deposits, such as the Bangurdih, Garadiah, Nimdih, Rajgaon, Kanyaluka and other deposits of the Singhbhum Shear Zone, which require separate infrastructure and independent considerations for mining and processing, may be placed under the UNFC 2009 subclass “Development unclarified”. The economic viability of these deposits warrants very favourable socio-economic consideration. These deposits are not reasonable prospects for economic extraction in the foreseeable future, and thus may be categorized as E3.2, F2.2, G1,2,3. These quantities are estimated to be 33% of the resources in the SSZ.

Other deposits

78. Tummalapalle and its adjoining area in the Southern Cuddapah basin report more than 70,000 t U of carbonate-type resources. Host rock characteristics and the lower grade of these deposits make them economically less attractive. But considering their large tonnage, extraction is expected to be sustainable in some part of these deposits. Implementation of the project at Tummalapalle is

underway for a part of the indicated resources; studies are in progress for Tummalapalle extension blocks. UNFC code of E1.2, F1.2, G1, 2 for 17% of the resources of the basin at Tummalapalle; E2, F 2.1, G1,2,3 for 18% of the resources for extension of Tummalapalle; and E2, F2.2, G1,2,3 for the remaining resources of the adjoining area has been proposed (Table 11).

Table 10. Uranium resources of the Singhbhum Shear Zone, India

Deposits	UNFC-2009 Class	UNFC-2009 Sub-Class	UNFC-2009 Categories		
			E	F	G
Jaduguda, Bhatin, Narwapahar, Bagjata, Turamdih, Banduhurang and Mohuldih	Commercial Projects	On production	1.1	1.1	1,2
Banadungri-Sinidungri, extensions of Narwapahar and Jaduguda	Potentially Commercial Projects	Development on Hold	2	2.2	1,2,3
Bangurdih, Garadih, Nimdih, Rajgaon, Kanyaluka and others	Non-Commercial Projects	Development Unclarified	3.2	2.2	1,2,3

79. The unconformity related deposits in the northern Cuddapah Province are also of low grade resources. Project activities are in progress for the development of some of these deposits. The geological aspects of these deposits are fairly well understood. A UNFC-2009 code of E2, F2.1, G1,2,3 has been proposed for some of the Northern Cuddapah uranium deposits.

80. Uranium resources in North Delhi Fold Belt (NDFB) Province are also of low grade and the national economic considerations could permit extraction in future, subject to favourable findings in feasibility studies. Geological characteristics of these resources are fairly well established. A UNFC-2009 code of E2, F2.2, G1,2,3 is proposed for NDFB resources.

81. Uranium resources in the Bhima Basin are of medium grade and unconformity related. Implementation of the mining/extraction in this area is subject to some more technical studies and favorable socio-economic consideration. The geological aspects of the deposit have been fairly well understood and a UNFC-2009 code of E2, F2.1, G1,2 has been proposed for Bhima Basin resources.

82. The sandstone-type deposits in Mahadek Basin in the State of Meghalaya are of low to medium grade and amenable for open pit mining. Geological aspects of these deposits have been adequately studied. A UNFC-2009 code of E2, F2.1, G1,2 is proposed for the resources at KPM (Domiasiat), which account for about 47% of the basin, and E3.2, F2.3, G2,3 for remaining resources (Wahkyn-Tyrnai-Umthongkut-Gomaghat - II and others of Mahadek Basin) is proposed.

Table 11. Uranium resources of other deposits in India

Deposits	UNFC-2009 Class	UNFC-2009 Sub-Class	UNFC-2009 Categories		
			E	F	G
Tummalapalle Basin	Commercial Projects	On production	1.2	1.2	1,2
Tummalapalle Extension	Potentially Commercial Projects	Development Pending	2	2.1	1,2,3
Adjoining areas of Tummalapalle	Potentially Commercially Projects	Development on Hold	2	2.2	1,2,3
Northern Cuddapah	Potentially Commercial Projects	Development pending	2	2.1	1,2,3
North Delhi Fold Belt	Potentially Commercial Projects	Development on Hold	2	2.2	1,2,3
Bhima Basin	Potentially Commercial Projects	Development Pending	2	2.1	1,2
KPM (Domiasiat) of Mahadek Basin	Potentially Commercial Projects	Development Pending	2	2.1	1,2
Wahkyn-Tyrnai-Umthongkut-Gomaghat – II and others of Mahadek Basin	Non Commercial Projects	Development not viable	3.2	2.3	2,3

Exploration projects

83. Quantities estimated in several Exploration Projects totalling 84,800 t U [2] have been assigned UNFC-2009 codes of E3.2, F3, G3,4.

Conclusion

84. The advantages of applying UNFC-2009 lies in its simplicity to quantify the judgment in a coded manner, which can be best understood and uniformly interpreted by professionals. It also provides a linkage to business processes and decision making. In the Indian uranium industry, although it has not yet become mandatory to report the status of project using the UNFC-2009 system, the usefulness has been aptly realized by the professionals. However, it may not be complex to report the status of all mines/deposits/occurrences in this system while maintaining the existing system of reporting, since the industry is appropriately structured and well-regulated. The industry has a large base of experts/professionals to address complex issues on uranium exploration and mining in the country.

F. URANIUM IN MALAWI: CASE STUDY ON THE APPLICATION OF UNFC-2009

Prepared by Cassius Chiwambo, Senior Mining Engineer – Ministry of Natural Resources, Energy and Mining, Malawi.

Role of extractive industries in Malawi's economy

85. Malawi, in southeastern Africa, occupies a thin strip of land between Zambia and Mozambique protruding southwards into Mozambique along the valley of the Shire River. In the north and northeast it also shares a border with Tanzania. Malawi is connected by rail to the Mozambican ports of Nacala and Beira.

86. Malawi's economy has for many years been agro-based and this industry did not have the needed muscle to increase the country's economy. Following the need to expand its economic base, Malawi made a firm decision to promote extraction of its mineral resources. Despite its previous idleness of the mining sector, which was as a result of lack of interest by the immediate post-colonial Government who focused on putting in place policies that promoted the agricultural sector, Malawi is now becoming one of the active mining countries in Africa, as evidenced by the various exploration and mining activities taking place currently.

87. The country's macro-economic vision is indicated in the Malawi Growth and Development Strategy (MGDS). In this strategy, the Mining Sector is pointed out as one of the key priority sectors for economic growth. In view of this strategy, the Government's policy direction is to have:

- A viable and transparent fiscal and taxation regime that attracts investors in the minerals sector and ensures that a substantial amount of revenue is retained in Malawi.
- A clear, transparent and equitable regulatory framework for the minerals sector.

88. This policy has resulted in massive exploration activities. From the exploration works, it has been revealed that the national geological endowment includes:

- High-value minerals, such as uranium, heavy-mineral sands (HMS), rare earth elements (REEs), niobium, zircon, and tantalum;
- Industrial minerals, such as phosphate, bauxite, gypsum, limestone, silica sand and clays;
- Energy resources, such as coal and uranium; and
- Precious and semi-precious stones and metals, such as ruby, aquamarine, and tourmaline.

89. The country has the third largest lake in Africa, Lake Malawi. This lake is situated in the highly anticipated Petroleum Occurrence Zone (POZ), situated in the Great African Rift Valley, which has lately been proven to have a huge potential for petroleum in Africa; this potential is evidenced by the discovery of oil in Lake Albert, which lies in the same rift system.

90. Since 2004, Malawi intensified activities such as policy formulation and capacity building in the minerals sector. Lately, investment in Malawi's minerals sector has greatly increased. The Malawi government is committed to putting policies in place that will attract private sector participation in the exploration, exploitation, processing, and utilization of Malawi's mineral resources. To this end, in March 2013, the Mines and Minerals Policy of Malawi was approved and launched by the Malawi government. The government recognizes that the minerals sector has significant potential to contribute towards rapid economic growth and development of the country, as evidenced in its inclusion in the Malawi Economic Recovery Plan 2012.

91. The policy seeks to stimulate and guide private mining investment by administering, regulating and facilitating the growth of the sector through a well-organized and efficient institutional framework. The government will also intensify provision of extension services to the artisanal and small-scale miners and women miners. The goal of the Mines and Minerals Policy is to enhance the contribution of mineral resources to the economy of the country, so as to move from being an agriculture-based economy to a mineral-based economy.

92. Currently, mineral production includes brick clay, coal, crushed stone, limestone, uranium, gemstones and ornamental stones (amethyst, garnet, ruby, sapphire, tourmaline, agate and rose quartz) [44]. Five coal mines are currently producing in Mchenga, Nkhachira, Kaziwiziwi, Eland and Lufira. Gemstones are being exploited in various mines in the Mzimba District and Nyala at Chimwazulu Hill. Limestone is being mined in Wimbe. A phosphate mine is located in Tundulu. Uranium mining and milling has been carried out in Kayelekera, but this operation is currently on standby status due to reductions in uranium prices.

93. In addition to this resource production, exploration is ongoing for gold, niobium, tantalum, titanium, zirconium, graphite, rare-earth elements and uranium.

94. In 2009, Malawi entered the international family of uranium producers with the start of operations at the Kayelekera Uranium mine in Karonga, which is being operated by Paladin Africa Limited. That event signalled a change in the wider fortunes of the African region as a uranium producer. In 2012, nearly 2% of the world uranium production came from Malawi. Uranium accounted for 8.4% of Malawi's exports by value in 2011. It is now estimated that in production terms, Africa as a whole will be the fastest growing region for uranium production [2].

95. All mining activities are under the control of the Ministry of Natural Resources, Energy and Mining with environmental matters falling under the Department of Environmental Affairs in the same ministry. As more new discoveries of mineral deposits are being reported, the government realizes its capacity shortfalls to efficiently regulate the sector. Despite intensifying its own capacity of building initiatives, which are also being supported by the international organisations such as the IAEA and the government's cooperating partners, the exponential growth of the sector needs a consequent exponential growth of the government's skills in managing it.

96. All mining activities are under the control of the Department of Mines of the Ministry of Natural Resources, with environmental matters falling under the Department of Environmental Affairs in the same ministry. As more new discoveries of mineral deposits are being reported, the government realized its capacity shortfalls to efficiently govern the sector. Despite intensifying its own capacity building initiatives, which are also being supported by the international organizations such as the IAEA and the government's cooperating partners, the exponential growth of the sector needs a consequent exponential growth of the government's skills in managing it.

Challenges in mineral resources reporting

97. One of the challenges that Malawi is facing is in the reporting on the mineral resources because they are reports by exploration companies. Malawi's normal procedure is to give investor's

the freedom to report its exploration discoveries using the system that it prefers. At the end of the day the government is mandated to know the resource findings for its own planning purposes, as well as reporting this data to other institutions, such as the Minerals Yearbook prepared by U.S. Geological Survey (USGS). Thus, government officials need to know and understand the various reporting systems. This has proven to be a great challenge.

98. The Mines and Minerals Act in ‘The first Schedule’ provides that it is the duty of the holder, or former holder of a Mineral Right to furnish information, submit reports or keep records. By having this provision, investors have been submitting reports using the format of their choice. This has been a challenge for the government, for its harmonised interpretation of the submitted reports entailed multi-skilled professionals to interpret such reports. Due to lack of such multi-skilled professionals in the sector, the government has been facing challenges in interpreting all of the submitted reports within the shortest period as it sometimes relies on sourcing experts to do the interpretation where necessary. Following this challenge, government made a decision to find a suitable reporting system for government’s purposes that will link with the formats generally used by investors. The government could then encourage the investors to use this reporting system for its purposes only.

99. Several systems were studied and some systems were found critical to several investors. During this exercise, it was noted that if one existing system (already being used by the companies in Malawi) was to be chosen; it meant the government was to either force or convince the other investors to adopt the one system that was recommended from the government’s perspective. This development was seen to be difficult and could result into suspicion and conflict of interest, because government is not required to operate in such a manner.

100. A further search was done and it came to the point when the Government became aware of the existence of the United Nations Framework Classification for Fossil Energy and Mineral Reserves and Resources 2009 (UNFC-2009).

101. The Government of Malawi studied the UNFC-2009 classification system; it made a basic analysis of the country’s reported mineral resources by applying the UNFC-2009 categories and Classes. As an example, the REE resources in Malawi could be classified as shown in Table 12.

Table 12. REE Projects in Malawi

Uranium resources of Malawi

102. One of the major uranium deposits in Malawi is the Kayelekera Deposit. In the early 1980s, the Department of Geological Surveys discovered uranium mineralization in the sandstone of

Kayelekera. Thereafter, the Central Generating Board of Great Britain (CEGB) evaluated the deposit. Extensive drilling conducted from 1982 to 1988 defined an initial inferred resource of 9800 tU at an average grade of 0.13% U [2].

103. The Kayelekera uranium deposit is a sandstone-hosted uranium deposit, located close to the north tip of the North Rukuru Basin. This basin contains a thick (at least 1 500 m thickness) sequence of Permian Karoo sandstones preserved in a semi-graben, located about 35 km to the west of, and broadly parallel to, the Lake Malawi section of the East African Rift System.

104. Historical studies indicate that economically recoverable resources of uranium and coal exist within the Kayelekera area. Coal is present in the project tenement area in two deposits: the Nkhachira Deposit and in association with the Kayelekera Uranium Deposit. Coal in the Kayelekera Deposit is contained within the uranium resources and is therefore unavailable for commercial extraction. Moreover, this coal is of very low quality.

105. Kayelekera is the first mine to have produced uranium in Malawi and is currently the only producer (Figure 12).

106. Another potential uranium resource is the Kanyika Niobium Project held by Globe Metals. Uranium is an important by-product in the complex polymetallic ore within a pegmatite quartz vein, hosted in Proterozoic felsic schists. Niobium and tantalum products would be produced with uranium and zircon as by-products.

107. Following an analysis of Malawi's preparedness and priorities for the operation of its minerals sector, with focus on radioactive minerals, in 2013 an IAEA expert team found that Malawi had a good position to enter into such an important sector (Table 13).

Figure 12. View of the Kayelekera Uranium Mill, Malawi (Photo C. Chiwambo, Malawi)

Classification of uranium resources

108. Kayelekera is currently the only uranium producing project in Malawi. Quantities estimated as “Commercial Project” (E1F1.1G1,2) amount to 5,398 t U. Additionally, 11,014 t U is estimated as a “Potentially Commercial Project” (E2F2.1G1,2,3). Aggregate quantities of the deposit under both

the classes amount to 16,412 t U (Table 14). The quantities are adjusted for depletion for mining to the end of June [45].

109. The Kayelekera Project was placed on care and maintenance in February 2014 due to depressed uranium market conditions. The production has been suspended until sustained uranium price recovery occurs [45]. Since the project is maintaining the operational readiness to come to operation any time in the future, it may be designated as E1F1.1 under UNFC-2009. It can be further classified as “Developed Non-Producing”, analogous to petroleum projects described in the Bridging Document between PRMS and UNFC-2009 [12].

110. A high level of granularity is possible when using UNFC-2009. For regional development and sustainable planning of the project, this level of precision in reporting can be highly useful.

111. At a national level for governmental planning purposes, a lower level of granularity could be sufficient. All the uranium projects of Malawi can be classified under UNFC-2009 as shown in Table 15.

Table 13. Uranium projects - Country preparedness and priorities, Malawi

Country	Status by Milestone Achieved	Geology & Exploration	Resource Evaluation & Reporting/ UNFC-2009 and NEA/IAEA Red Book	(Pre)- Feasibility, EIA, EMP and Production, including CX, HSE	Critical Dependencies/C CP	Actions
Malawi	On Production/ Development Pending/ Exploration Projects	High potential in Karoo; Uranium associated with Niobium	Newest producer of U in Africa, Kaylekeera; Second mining project in country; New project feasibility studies underway; Exploration projects	Mineral sector a priority now to reduce poverty. Issues with Mineral Development Agreements	Capacity in mineral development agreement; sustainable development of Uranium resources; social communications	IAEA lead international peer-review of uranium operations

CCP – critical control point; CX – comprehensive extraction; EIA – Environmental Impact Assessment
EMP – Environmental Management Programme; HSE – Health, Safety, Environment
UNFC-2009 – United Nations Framework Classification (2009)

Conclusions

112. UNFC-2009 is an effective tool for reporting and management of uranium at regional and national levels. Higher granularity is important when reporting individual projects, and the information at this level of detail is important when addressing socio-economic issues at a regional level. The scheme also allows aggregation of the total quantities for comprehensive understanding.

113. UNFC-2009 is particularly important for national reporting where data is assimilated from different company sources, both from public reports as well as direct communications to the government. While most of the public reporting is done under international schemes suitable for the respective companies. Many companies that do not need public reporting could communicate quantities of uranium and other commodities to the government under the UNFC-2009 scheme.

114. The sustainable development of mineral commodities, such as uranium as a by-product in the case of Kanyika Project, is not only important for Malawi, but also for the nuclear industry as a whole. The uranium recovered in this manner has the least mining foot-print, does not become a detrimental factor for the environment, and is likely to bring overall socio-economic gains for the country. Use of UNFC-2009 allows tracking of such sustainable possibilities, which is its major advantage.

115. The Government of Malawi's overall information on the minerals industry can be strengthened when the reporting also considers Non-Commercial Projects and Exploration Projects. These are the projects that could be expected to contribute to mineral production in the long term and thus have an impact on the economy over larger time-frames.

116. However, the effective use of UNFC-2009 needs comprehensive information on the principles, rules and guidelines. The associated bridging criteria to the existing reporting frameworks are also need to be understood for its effective use. Further improvement in capacity in use of UNFC-2009 is required for introducing such a new scheme.

117. Currently, Malawi has just finalized a comprehensive Airborne Geophysical Survey Exercise. In this case, depending on the positivity of the survey results, Malawi expects a huge in-flow of transnational, as well as domestic investors, who will be interested in the information generated. This will mean a huge need for a homogenous reporting format, such as the use of the UNFC-2009. As such, the UNFC-2009 will very much benefit the country.

G. United States—A thorium source in the Mountain Pass rare earth elements deposit, California, United States, and the application of UNFC-2009

Prepared by Bradley S. Van Gosen, U.S. Geological Survey.

Introduction

118. Historically, uranium and thorium deposits worldwide have been classified and reported according to the resource reporting scheme developed by the Nuclear Energy Agency of the Organization for Economic Co-operation and Development (NEA) and the International Atomic Energy Agency (IAEA). This system consists of a biaxial classification that considers the degree of geological knowledge and the production costs of uranium concentrate and (where applicable) thorium concentrate.

119. Thorium, similar to uranium, can be utilized as a nuclear fuel. Despite numerous projects and several pilot test reactors in several countries designed to evaluate thorium as a viable reactor fuel, thorium-based nuclear power has yet to be fully commercialized. Currently, research and development is being carried out on several concepts for advanced reactors including: high-temperature gas-cooled reactors (HTGR); molten salt reactors (MSR); Candu-type reactors; advanced heavy water reactors (AHWR); and fast breeder reactors (FBR). Federal government-supported projects, particularly in India and China, are focused on the development of thorium-based nuclear power [2]. Based on these activities, utilization of thorium as fuel is expected after 2020.

120. Because of the low demand for thorium, it has not been a primary target of exploration in the past. The research and development efforts mentioned above may increase the demands for thorium and likewise increase national and global evaluations of thorium deposits.

121. Mineral deposits that are rich in the rare earth elements (REEs) typically also contain anomalous enrichments in thorium. Primarily for this reason, the most likely sources of thorium in the foreseeable future will come from the recovery of thorium as a co-product of the mining and processing of REE deposits.

122. Production of REEs during the 1950s to the late 1980s came primarily from the United States, India, South Africa and Brazil. In 1927, Chinese geologists discovered REE deposits at Bayan Obo in the Inner Mongolia Autonomous Region. Mines and processing plants built at Bayan Obo began to produce REE concentrates in 1957 [49]. By 2002, China became the dominant producer of REEs in the world [49]. During the more than 80 years following the discovery of Bayan Obo, REE deposits were found in 21 of China's Provinces and Autonomous Regions [49]. In 2009, China reported its domestic extractable quantities of REEs as 18.6 million metric tons of REE oxide [50, p. 410]. China introduced a production quota on their REE industry in 2008 [49], which triggered a worldwide look for REE deposits in other countries. In recent years, deposits of REE resources have been assessed in Australia, Brazil, Canada, China, Finland, Greenland, India, Kyrgyzstan, Madagascar, Malawi, Mozambique, South Africa, Sweden, Tanzania, Turkey, the United States, and Vietnam [51] [52] [53].

123. Actively mined REE ore deposits are economic on the basis of their REE production. Co-existing thorium-rich minerals could be evaluated as sources of by-product or co-product thorium if a market develops for thorium in the future. For now, the production of thorium as the primary product is thought to be uneconomic [2]. In the context of production, a by-product can be defined as the "output from a joint production process that is minor in quantity and/or net realizable value (NVR) when compared to the main products" [54]. By convention, by-products also are not inventoried, but the NRV from by-products is typically recognized as 'other income' or as a reduction of joint production processing costs when the by-product is produced. Co-product on the other hand is a major

output from a joint production process that is significant in quantity and/or NVR. Co-products play an important role in the economic analysis of a mineral project.

124. In most REE-thorium-rich deposits, the most common thorium-bearing mineral is monazite, a REE–thorium–phosphate mineral. Thus, most of the thorium content in the majority of REE deposits is due to monazite, only occasionally due to other thorium-rich minerals, such as thorite (thorium silicate). Monazite can contain as much as 20 percent thorium oxide [55]; hence, thorium may be evaluated as a co-product in many REE deposits containing monazite.

125. Moreover, policy objectives of waste hierarchy, such as the European Union Waste Framework Directive (established in 1975 and revised in 2008), mandate disposal as the last and least desirable of the management options of any process residues [56] [57]. Reuse, recycling, energy recovery, and other potential uses are to be considered before materials are assigned as waste and presumptively disposed.

126. Monazite concentrate production is currently taking place in India, Malaysia, Vietnam, and Brazil, in decreasing order of production [52]. The Indian Bureau of Mines describes India’s coordinated effort to recover monazite from heavy-mineral sands then chemically treat the monazite to separate rare earths in composite chloride form and thorium as hydroxide upgrade [58]. The planned capacity of the monazite processing plant was established at 10,000 t per year in 2011, expected to be increased to 20,000 t per year in the future [58]. The recovery of thorium from monazite-rich ore is being considered for the Steenkampskraal Deposit in South Africa, which is a REE mining and production project under development in 2014 [59] [60].

127. The co-product occurrence of thorium and a general lack of economic interest in thorium have meant that thorium quantities were rarely, if ever, accurately defined in most countries. Information on estimated quantities of thorium was published between 1965 and 1981 in the biennial publication the “Red Book”, published jointly by the NEA and IAEA; the thorium estimates reported in these reports applied the same terminology as was used for uranium resources at that time.

128. In 2012, the United States reported identified domestic thorium quantities (in situ) of about 434,000 t of thorium [2]. The principal thorium deposit types in the United States are vein-type, carbonatite-hosted, and placers [61].

129. UNFC-2009 allows the documentation and reporting of estimated known, inferred, and undiscovered thorium quantities. The UNFC-2009 classification scheme, in addition to providing the project maturity of mineral commodities, considers social and economic issues, including regulatory, legal and market conditions imposed by governments and markets, domestic demand, technological and industrial progress, as well as ever-present uncertainty of the foreseeable future.

Case study—Mountain Pass Deposit, California, USA

130. This case study presented here is a UNFC-2009 classification of a rare earth elements-thorium deposit in California, United States, classifying the deposit as both a source of rare earth elements (REEs) and as a potential source of thorium. Specifically, the deposit used in this example is the REE ore body developed by the Mountain Pass mine in southeast California, owned and operated by Molycorp Inc. (<http://www.molycorp.com/>) (Figure 13). The mine and onsite mineral processing plants exploit the largest known REE deposit in the United States—the Sulphide Queen carbonatite [62]. After an eight-year hiatus, Molycorp reopened operations at the mine in late 2010. The mining and ore-processing operations at Mountain Pass remain active at this time (2015); Molycorp announced goals of increased production in 2014.

131. The REE ore body of Mountain Pass represents a potential future source of thorium as a co-product of REE production. The thorium content in this ore body is primarily due to the mineral

monazite, which is intimately intergrown with the REE ore minerals. Monazite concentrations range throughout the ore body from trace amounts to locally abundant [62].

132. Molycorp Inc. reports that the Mountain Pass ore body—the Sulphide Queen carbonatite—contains Proven and Probable Reserves of 16.7 million tonnes of ore with an average grade of 7.98 percent REE oxides, applying a cut-off grade of 5 percent REE oxides [63]. A recent U.S. Geological Survey reconnaissance bulk sampling of ore exposed in the open-pit mine (about 1 metric ton of composited ore was collected) found an average thorium content of approximately 0.025 percent within high-grade REE ore; this value is nearly identical to the thorium concentrations found in earlier geochemical studies of this carbonatite [64]. This thorium concentration suggests that each tonne of ore mined from the deposit contains roughly 0.25 kilograms of thorium on average. This estimate of Th content in the Sulphide Queen ore body is certainly an approximation based on limited sampling; monazite concentrations may prove to vary considerably across the carbonatite ore body as mining progresses. For discussion purposes, applying an ore body estimated to comprise at least 16.7 million tonnes of carbonatite, with an average thorium content of about 0.025 percent, there would be an estimated resource of at least 4200 tonnes of thorium at Mountain Pass. Since the estimates are based on limited sampling and extrapolation, it should be considered as an estimate in the lowest level of geological confidence.

133. The mining and processing operation at Mountain Pass is currently devoted only to the recovery and separation of REEs. No plans have been reported by the company to recover the thorium in the foreseeable future. At this time (2015), when the carbonatite of Mountain Pass is mined, processed, and the REEs are separated, the thorium moves with other residues into the tailings impoundment. Thus, it would require modification of the process flow-sheet and/or further reprocessing of the tailings in order to recover the thorium in the future.

Classification of the case study according to UNFC-2009

134. As a mine and production operation for REEs, the Mountain Pass mine of Molycorp would be classified using UNFC-2009 as E1.1 F1.1 G1,2. That is, on its basis as a rare earth element operation, it is classified by these categories and sub-categories (Table 16):

E1.1 “Extraction and sale is economic on the basis of current market conditions and realistic assumptions of future market conditions.”

F1.1 “Extraction is currently taking place.”

G1, G2 “Quantities associated with a known deposit that can be estimated with a high level of confidence” (Proven Reserves) and “with moderate level of confidence” (Probable Reserves).

135. In contrast, viewed additionally as a known, unutilized thorium deposit sampled for thorium content at a reconnaissance level, this mineral deposit may be classified as E3.3 F2.3 G3:

E3.3 “On the basis of realistic assumptions of future market conditions, it is currently considered that there are not reasonable prospects for economic extraction and sale in the foreseeable future.”

F2.3 “There are no current plans to develop or to acquire additional data at the time due to limited potential.”

G3 “Quantities [of thorium] associated with a known deposit that can be estimated “with a low level of confidence.”

Conclusion

136. The application of UNFC-2009 as a complement to the NEA/IAEA Classification contributes to both a better understanding of the availability of thorium in the United States as well as providing information on how these sources may contribute to future planning and enactment of nuclear energy programmes.

Figure 13. The Mountain Pass mine of Molycorp, Inc. in South-east California. This is the only active REE mine in the United States (in 2014). The ore body is a carbonatite intrusion, thought to represent the largest REE resource in the United States. (Photograph by B. Van Gosen, USGS).

H. United States—Coles Hill Uranium Deposit, Virginia, and the application of UNFC-2009

Prepared by Susan Hall, U.S. Geological Survey.

Introduction

137. The case study presented here reviews the uranium resource estimates and summarizes the property situation of the Coles Hill uranium deposits. Uranium resources at Coles Hill are then classified following the UNFC-2009 system.

138. The Coles Hill deposit is located in Pittsylvania County, southern Virginia, USA (Figure 14). Coles Hill was discovered by the Marline Corporation who identified an outcropping surface radiometric anomaly in 1979. The deposit was delineated by Marline and UMETCO (a subsidiary of the Union Carbide Corporation) from 1979 to 1984. In all, 182 rotary holes (38,037 m (124,799 feet)) of drilling and 74 core holes (19,836 m (65,082 feet) of drilling) were completed and define two distinct deposits, the North and South Coles Hill deposits [65]. Marline let their option to develop the property lapse in response to low uranium prices and a moratorium on uranium mining in Virginia that was passed in 1982. In 2006, a corporation formed by the majority property owner, Virginia Uranium LLC, consolidated 2,296 acres (929 hectares) in surface rights and 2,940 acres (1190 hectares) in mineral rights, which cover most of the north and south deposits. In 2008, Virginia Uranium drilled 3 core and 7 rotary holes, and re-logged 5 historic holes geophysically, to confirm earlier results. The Marline core was donated to, and is curated by, the Virginia Natural History Museum; the Marline core is stored on site along with the core drilled in 2008 by Virginia Uranium. Access to the property is good over secondary paved roads, and there is excellent infrastructure in the region.

Geology

139. The deposits are hosted in Ordovician mylonitic quartzo-feldspathic orthogneiss and amphibolite of the Martinsville Intrusive Suite. Mineralized zones are characterized by sodium metasomatite alteration, chloritization, and hematization. The deposits are bounded by the Chatham Fault to the southeast, which marks the edge of a Triassic basin, and to the west and at depth by the Fork Mountain Schist (Formation) (Figure 14). The deposits are about 350 meters long and 250 meters wide [65]. The North Coles Hill deposit plunges about 20 degrees northeast, with mineralization identified at least 305 m (1000 feet) below the surface, and the South Coles Hill deposit plunges about 30 degrees southwest, with known mineralization to about 550 m (1800 feet) below the surface [66]. Mineralized zones range from three to over 30 meters thick along an interval 30 to over 60 meters in length [66].

Resource estimates

(A) Historic resource estimates

140. The first “reserve calculation” was completed by Pincock, Allen and Holt for the Coles Hill deposit in 1982 [67]. The in situ resource was estimated with cutoff grades from 0.150 to 0.025% U_3O_8 . This estimate used cross section and geologic correlation methods of interpretation coupled with a combination of down-hole gamma logging and chemical assays [67]; estimated resources are summarized in Table 17. In 1984 another uranium resource was estimated for the south Coles Hill deposit by the UMETCO Minerals Corporation. The estimate calculated resources at cutoff grades of 0.150 to 0.05%, utilizing polygonal estimation coupled with kriging; these estimates are also summarized in Table 17. UMETCO did not calculate reserves at the lowest cutoff grades applied by Pincock, Allen and Holt [67], nor did they estimate resources in the North Coles Hill deposit. UMETCO engineered a pit design, and applied this model to the South Coles Hill deposit; they

estimated recoverable reserves at 11 million lbs U₃O₈ at a cutoff of 0.150 % U₃O₈, and 30 million lbs U₃O₈ at a cutoff of 0.050 % U₃O₈ [67].

Figure 14. Location and regional geology of the Coles Hill uranium deposit, southern Virginia, USA. Modified from [68].

³ Estimated by Behre Dolbear, CIM standardized, NI 43-101 compliant [67].
⁴ Estimated by Lyntec Inc. and BRS Engineering, CIM standardized, NI 43-101 compliant [66].

(b) Mineral resource estimates

141. The 1980s era resources are termed historic and are generally not relied upon by the modern mining industry or financial community until verified by independent testing and estimated following standards set by the Canadian Institute of Mining, Metallurgy, and Petroleum Definition Standards on Mineral Reserves and Mineral Resources (CIM). Once standardized to CIM specifications, the resource is compliant with Canadian National Instrument 43-101 (NI-43-101) and deemed reliable. Companies operating in the U.S. typically follow Canadian securities guidance because it was developed specifically for the mining industry, and a great deal of exploration capital is generated through Canadian-based resource companies.

142. In 2007, a Technical report in compliance with NI 43-101 was prepared for Coles Hill [65]; however, this report did not include an updated resource estimate. In 2008, Behre Dolbear produced the first NI 43-101 compliant resource estimate [67]. Measured resources were calculated within a radius of 15 meters from a drill sample, and indicated resources were those from 15 to 60 meters from a drill sample. A 3-dimensional block model was constructed and modelled using inverse distance techniques with data input from only those drill holes that had been chemically assayed and whose drill orientation was known. The results were reported as an in-situ resource with no property restrictions, recovery or dilution factors or economic considerations. Plan and cross-section views of the deposits as represented by the block model created for this resource estimate are shown in Figures 15 and 16.

143. In 2013 a new ore resource estimate and preliminary economic assessment were completed for the deposits [66]. Additional downhole data, not available for the 2008 assessment, were used in this estimate. As well, drill holes without known survey data, excluded in the 2008 estimate, were used and considered as having been drilled vertically. A more detailed block model was constructed and kriging was used to incorporate geochemical data into the model. The results of this resource estimate are summarized in Table 17. The preliminary economic assessment was based on only a portion of this resource. For mine design, indicated resources using a cutoff of 0.06% U_3O_8 were selected. Although both surface and underground mining were considered, for this study an underground mine was designed. Further studies were recommended that might utilize a combination of open pit and underground methods of extraction, and this would change the economic analysis of the deposit.

144. The preliminary economic assessment concluded that at a price of USD 64/lb U_3O_8 (USD 166/kg U) and based on current understandings of the continuity of ore, and a number of other factors considered in the report, the deposit was economically viable. The primary risk related to mining of the deposit continued to be the 1982 moratorium on uranium mining in Virginia, which is still in effect [66]. Because of this moratorium, mineral resources at Coles Hill cannot be classified as reserves.

CIM, NEA/IAEA and UNFC-2009 classification of resources at Coles Hill

145. Indicated mineral resources used in the feasibility study of the resources at Coles Hill, as well as the total indicated and inferred resources not included in the feasibility study, are used as a basis for classification in Table 18 [66]. These resources are classified in the CIM, NEA/IAEA and UNFC-2009 systems. Indicated resources in the CIM system are equivalent to Reasonably Assured Resources in the NEA/IAEA System [2]. The feasibility study of the deposits is based on a uranium price of USD 64/lb U_3O_8 (USD 166/kg U), therefore the cost category under the NEA/IAEA system is USD < 260/kg U (USD 100/lb U_3O_8). For indicated resources not included in the feasibility study, the forward cost category is unknown. The NEA/IAEA system recognizes inferred resources as a separate category (Table 18).

Figure 15. Plan view of the north (NCHD) and south (SCHD) deposits as represented in a block model using a 0.1% U_3O_8 cutoff [67].

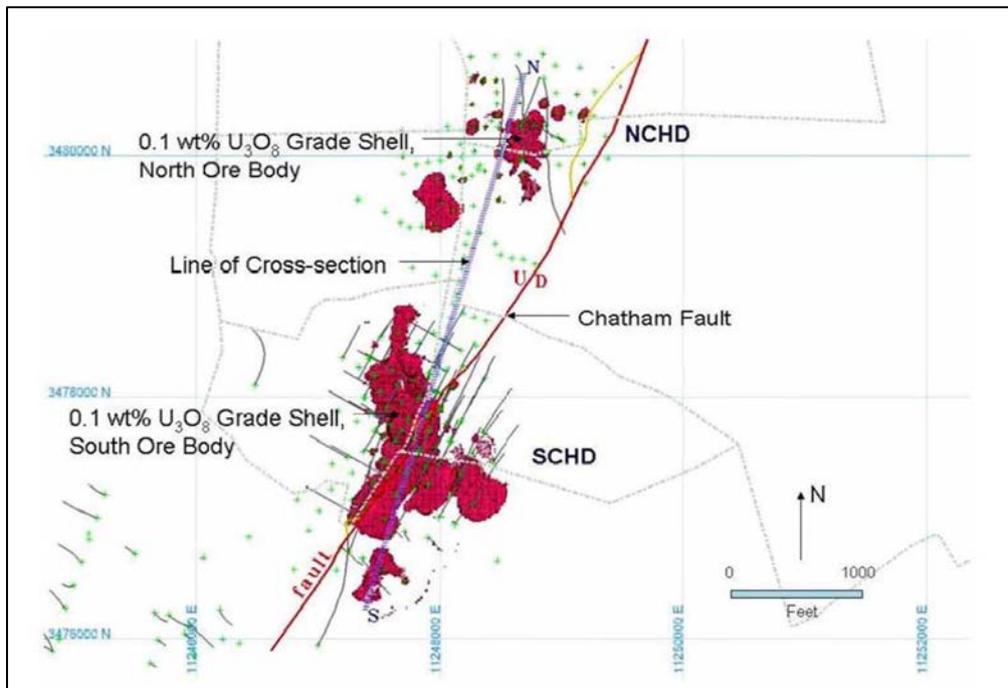

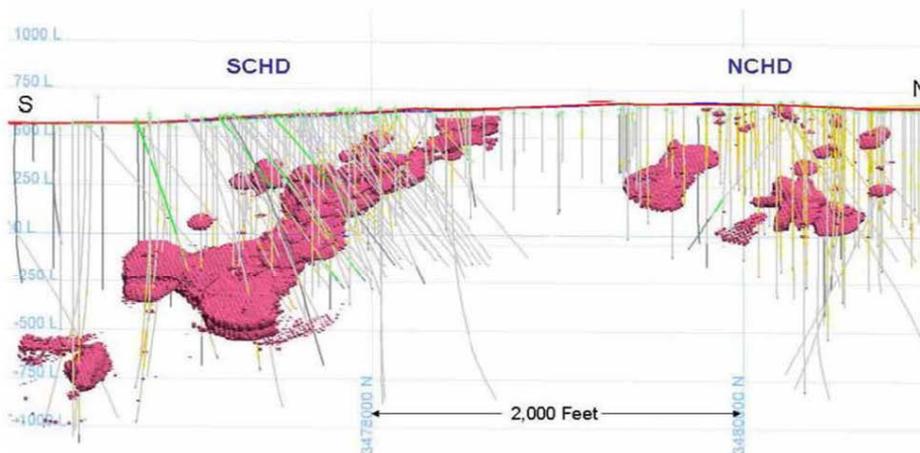

Figure 16. Cross section view of the north (NCHD) and south (SCHD) deposits as represented in a block model using a 0.1% U_3O_8 cutoff [67].

146. UNFC-2009 provides a mechanism to categorize projects based on project feasibility (F), geologic certitude (G) and socio-economic viability (E). When considering feasibility (F), Indicated resources with a grade cutoff of 0.05 % U_3O_8 used in the preliminary economic assessment of Coles Hill would fall into the F 2.2 category (Table 18). This classification is most appropriate because project activities are on hold awaiting justification for commercial development pending improvements in price and access. Considering separately the total indicated resources and inferred resources, these would be likewise classified as F 2.2.

Table 18. Mineral resources of the North and South Coles Hill Deposits (combined) as classified in the CIM, NEA/IAEA and UNFC-2009 classification systems.

Million pounds U ₃ O ₈ ¹	Cutoff Grade (%U ₃ O ₈)	CIM Classification	NEA/IAEA Uranium Resource Classification	UNFC-2009 Categories			UNFC-2009 Class	UNFC-2009 Sub-Class
				E	F	G		
64 ²	0.06	Indicated Resource	Reasonably Assured Resource (RAR) that could be produced for <USD 260/kg U	3.3	2.2	2	Non-Commercial Project	Development not viable
132 ³	0.025	Indicated Resource	Reasonably Assured Resource with unknown cost category	3.3	2.2	2	Non-Commercial Project	Development not viable
30 ³	0.025	Inferred Resource	Inferred Resource	3.3	2.2	3	Non-Commercial Project	Development not viable

¹ Note the total resource estimated for the Coles Hill deposits is not the sum of entries in this column. See Table 17 for a summary of the mineral resources estimated for the deposits.

² Portion of those indicated resources used for mine design and the preliminary economic assessment of the Coles Hill deposits [66].

³ Total Indicated and Inferred Resource for the Coles Hill deposits as calculated by Lyntec Inc. and BRS Engineering [66].

147. When considering geologic certitude (G), indicated resources are moderately well understood based on projections made a relatively short distance from known mineralization (drill holes) and would therefore be classified G 2. Estimates of inferred resources at Coles Hill are poorly defined because of limited drilling and an incomplete understanding of the continuity of mineralization and would fall into category G 3.

148. Finally, when estimating socioeconomic viability (E) of resources at Coles Hill, all resource categories at Coles Hill are best categorized as E 3.3 because those resources are a) not economic at current market conditions, nor b) extractable due to a moratorium on uranium mining in the state of Virginia. Even if the resource at Coles Hill could be extracted economically, it will not be extracted due to the moratorium and is not therefore expected to be available for sale in the foreseeable future. There is great uncertainty in this particular classification category due to fluctuations in uranium prices and vagaries of political limitations on mining. If there were no moratorium on mining, resources in these categories would probably rise to the E 2 category. In the situation where the mining moratorium was lifted, extraction would be feasible in the foreseeable future if uranium prices rise, thereby justifying this reclassification into E 2. If this moratorium is lifted, and prices climb to closer to the price used in the pre-feasibility model, the classification in this category could change quickly and significantly. However, currently because of the E 3.3 classification, this project would be considered “non-commercial”, with a UNFC subclass of “development not viable”.

Conclusion

149. Examination of historic resource estimates and modern feasibility studies based on mineral resource classification systems used in the 1980s and NI 43-101 compliant classification systems for the Coles Hill deposits provide an incomplete understanding of the viability of the project. A moratorium on uranium mining in the state of Virginia adds another level of uncertainty to the probability that this resource will be produced in the foreseeable future. Applying UNFC-2009 to classify mineral resources estimated for the Coles Hill deposits illustrates how this system can add an increased level of understanding of the resource by reflecting the impact the moratorium has on the socio-economic viability of the project. Because of this moratorium, and current low uranium prices, development of the project is currently not viable. However if the moratorium is lifted, the classification under UNFC-2009 would likely change as this level of uncertainty is removed.
