1) General description

1.1) Brief definition

This indicator shows the concentration of the following pollutants in coastal seawater and sediments.
- Coastal seawaters: ammonium nitrogen (NH₄), dissolved oxygen (O₂), oil hydrocarbons (OH), phenols, synthetic surface-active compounds (SSAC), chlorinated pesticides (CP), faecal coliform, and heavy metals (Cd, Co, Cu, Cr, Fe, Hg, Mn, Ni, Pb and Zn).
- Sediments: chlorinated pesticides, oil hydrocarbons and heavy metals.

1.2) Units of measurement

Concentrations of ammonium nitrogen are expressed in milligrams/litre; dissolved oxygen in milligrams O₂/litre; OH, phenols, SSAC, heavy metals and CP in micrograms/litre; and those of faecal coliform in MPN (Most Probable Number) per 100 ml. Concentrations of heavy metals, CP, and OH in sediments are expressed in micrograms/g of dry weight.

1.3) Context

Relation to other indicators from the Guidelines - This indicator relates to indicator “C-12: Nutrients in coastal seawaters”.

2) Relevance for environmental policy

2.1) Purpose

The indicator provides a measure of the state of coastal seawaters and sediments in terms of pollutant concentration.

2.2) Issue

The presence of pollutants in coastal seawaters and sediments poses a serious risk for the ecological state of coastal waters and indirectly for human health in coastal zones (via the
food chain). Large quantities of organic matter (microbes and decaying organic waste) as well as other pollutants can reduce the chemical and biological quality of water and result in an impaired biodiversity of aquatic communities and chemical and microbiological contamination. Chemical pollution results in accumulation of hazardous substances in aquatic fauna and flora. Sources of pollution include discharges from wastewater treatment plants, industrial effluents and agricultural run-off.

2.3) International agreements and targets

a) Subregional level

3) Methodology and guidelines

3.1) Data collection and calculations

A basic monitoring programme should specify pollutants and a core list of measured substances. The number of sampling points and their spatial location should enable the collection of information on the content of pollutants throughout the gradient of loads – from background water landing sea areas to coastal seawater areas exposed to substantive anthropogenic loads. In the case of a high number of sampling points on the coastal zone, the countries should select at least five representative points for the calculation of average concentrations to have a balanced representation of water quality or sediments. In order to take into account the time mutability of the content of biogenic substances, average concentrations should be reported for designated time periods in summer and winter for ammonium nitrogen and dissolved oxygen in coastal seawaters. Methodological and metrological uniformity of surveillance and data processing should be a goal; microbiological and chemical-analytical activities should be conducted by accredited laboratories with measurement quality control systems.
4) Data sources and reporting

The countries of South-Eastern and Eastern Europe, Caucasus and Central Asia have departmental and, in some cases, national databases of the level of pollution of coastal seawaters and sediments. Several coastal countries publish data on concentrations of pollutants in seawater, including coastal waters and sediments, in annual reports on marine environment quality.
