Inland Transport and Climate Change
a Literature Review

Alain Haurie∗†, André Sceia‡§ and Julien Thénie¶

November 3, 2009

Abstract

This paper contains a review of the recent scientific literature concerning inland transport and climate change. It is organized along the following topics: (i) current status and future trends; (ii) the role of transport in mitigation policies (technological options and life style changes); (iii) the vulnerability of transport infrastructure to damages due to climate change (impact and possible adaptation). The main results are reported and the possible gaps in the research activity in this domain are identified.

Keywords: Climate change, inland transport, literature review, mitigation, technology choices, fuel choices, life cycle analysis, adaptation, life style changes.

1 Introduction

This paper provides a summary of the scientific literature dealing with “inland transport and climate change”. It is based on a review of the most recent publications in this area of research. Our sources of documentation include the major scientific journals in relevant fields of research. A special focus is placed on “inland transport modes” which we define as encompassing terrestrial and fluvial transport (rail, road, inland waterways and oil pipelines). Thus, we shall not address in detail questions related to shipping or air transport.

An earlier review of the scientific literature on “transport and climate change” has been provided by Chapman (2007). It contains numerous references already provided in Hensher and Button (2003). Chapman (2007) organizes the review by mode (car, road freight, aviation, shipping, buses, walking and cycling) and focuses on the mitigation aspects of the problem. Complementary, Koetze and Rietveld (2009) undertook an extensive survey of the empirical literature in the impacts of climate change on the transport sector. In this paper we complement earlier reviews by presenting and analyzing the most recent publications in the field with a specific focus on inland transport modes.

In exploring the connection between inland transport and climate change we thus consider the following topics: (i) the current status; (ii) the role of transport in mitigation policies (technological options and life style changes); (iii) the vulnerability of transport infrastructure to damages due to climate change (impacts and possible adaptation).
2 Current status and future trends

2.1 Literature review

The transport sector is a major contributor to climate change. It is considered to be currently responsible of 23 % to 25 % of world energy-related GHG emissions (International Energy Agency (2009)), of which 65 % originates from road transport and 23 % from rail, domestic aviation and waterways (Chapman (2007)). Given current trends, transport energy use and CO2 emissions are projected to increase by nearly 50 % by 2030 and more than 80 % by 2050.

In light of the above facts and projections, it is not surprising that the topic of “transport and climate change” has already been extensively reviewed in several reports on top of being widely discussed in the peer-reviewed scientific literatures.

First, the chapter “Transport and its infrastructure” (Ribeiro et al. (2007)) of the contribution of the Working Group 3 to the Fourth IPCC Assessment Report, presents a detailed status, from the present and future energy consumption from the various transport modes (see figure 2) to the trends in car owner ship.

Second, the International Energy Agency (IEA) provides a multitude of reports of interests and collects a wide range of data of interest. Among recent publications, International Energy Agency (2009) discusses the prospects for shifting more travel to the most efficient modes and reducing travel growth rates, improving vehicle fuel efficiency by up to 50% using cost-effective, incremental technologies, and moving toward electricity, hydrogen, and advanced biofuels to achieve a more secure and sustainable transport future.

Thirdly, the European Environment Agency undertakes annually a broad review of the transport and the environment. The latest report (European Energy Agency (2009)) presents a rather dark picture of the environmental impacts of deals with transport and its impact on the recent evolution of environmental impacts of the transport sector in Europe.

Finally, the Stern Review (Stern (2006)) in its annex 7.a also presents the current status and future business as usual projections of transport relates GHG emissions based on similar sources as the IPCC AR4.

![Figure 2: Trends in transport sector greenhouse gas emissions by country 1990-2006 (European Energy Agency (2009))](image_url)
Chapter 5 Transport and its infrastructure

Sustainable Development, ‘Mobility 2030’, also developed a projection of transport energy consumption by region and mode (Figure 5.3). EIA’s International Energy Outlook 2005, as well as the WEO 2006 (IEA, 2006b) includes higher oil price assumptions than previously. Its projections therefore tend to be somewhat lower than those of the WBCSD/SMP reference case projection. The WBCSD/SMP reference case projection indicates a considerably higher 1.4% per year for OECD Europe. Japan, with its rapidly growing economy, is projected to see transport energy use grow at a rate of 4.7% per year during this period. In contrast, transport energy use in the mature market economies is projected to grow more slowly. EIA forecasts the USA to slow to 0.4% per year, because of slower population growth, high fuel taxes and significant improvements in efficiency. IEA projects transport energy in the United States to grow at a rate of 20% per year, personal travel and freight transport together rising to 88% of the total in 2025. In 2004, the transport sector produced 6.2 GtCO₂, with an aging population, high taxes and low birth rates, is expected to experience a considerable increase in transport activities.

The peer-reviewed literature also contains a number of interesting articles published recently, which nicely complement the information found in major reports. They generally target more specific aspects of the transport and climate change issue.

Among the major challenges for the transport sector highlighted in the various reports, car ownership is systematically considered a major one. Indeed, the car ownership trends in some developing countries are quite impressive. Han and Hayashi (2008) look at the potential for car ownership increase in China’s 31 provinces, taking into account current socio-economic transition and consider its likely effect on atmospheric pollution (notably, CO₂, CH₄, CO, NMVOC, NOₓ and SO₂) up to 2020. Their results indicate that not only “…the total number of private cars, but also the volume of related pollutant emissions will shoot up to considerably higher levels in the near future if recent behavioral trends and the present technical aspects of private car use persist. Despite the introduction of stricter controls on private car purchase and pollutant emissions, China will come under much greater pressure to cut back on emissions.”

Creuztig and He (2009) analyze a wider range of externalities of car transportation (e.g. congestion) restricting their scope to the city of Beijing and show that social costs induced by motorized transportation are equivalent to about 7.5–15.0% of the city’s GDP and underline the uncertainty of climate change costs. They nevertheless show that “…a road charge could not only address congestion but also has environmental benefits”.

On the political side of the Chinese transport growth, Hu et al. (2009) present an overview of the initiatives launched in energy supply and consumption and the challenges encountered in sustainable road transportation development in China. After having highlighted the trends from 2000 to 2007, where “China has witnessed a 156% increase in total motor vehicle stock, 51% increase in passenger traffic volume and 65% increase in freight traffic vol-

Figure 1: Projection of transport energy consumption by region and mode (Ribeiro et al. (2007))

The modal share of road freight transport in inland total freight transport (road, rail and inland waterways) has slowly increased over the years and is now 76%. In 2006, passenger cars accounted for 83% of the inland total passenger transport (passenger cars, buses and coaches, and trains), measured in passenger-kilometres (pkm).” Future publications might confirm that the recent economic slowdown has led to a decrease in transport activities.

ume”, the authors present a multitude of initiatives put forward by the Chinese government to control the growth and identify issues such as low emission standards and the higher relative costs of public transportation. They conclude by advising the government to “...strengthen fuel economy technology...”, “promote high efficiency vehicle market penetration” or “give priority to public transport in mega-cities” but also advice on the promotion of “large-scale commercialization of coal-based alternative fuels” which might not solve the climate problem if not associated to carbo capture and storage technologies.

In developed countries, the public awareness of the climate problem is considered a prerequisite to behavioral changes. In this context and on the basis of a questionnaire administered in the Sacramento, California metropolitan region, Flamm (2009) assesses the effects of environmental knowledge and environmental attitudes on the numbers and types of vehicles owned per household, annual vehicle miles traveled, and fuel consumption. Interestingly, he finds that “first, environmental knowledge and environmental attitudes are strongly related: respondents who indicate that protecting the natural environment is important to them know more about the environmental impacts of vehicle ownership and use. Second, environmental knowledge is significantly related to average fuel efficiency of household vehicles. The households of respondents who know more about the environmental impacts of vehicle ownership and use own, on average, more fuel-efficient vehicles. Third, environmental knowledge is not, however, associated with the ownership of fewer vehicles, less driving, or lower fuel consumption.” This underlines the gap between the awareness of the climate change problem and the actual actions and provides an additional rational to the use of economic instrument such as CO₂ taxes.

Chen and Zhang (2009) examine adoption of fuel efficiency technologies by the US automobile industry between 1985 and 2002 and consider the environmental implications. The analysis is based on the estimation of an efficient frontier between weight and fuel efficiency. They conclude that their analysis “shows that the technology efficient frontier of the US automobile industry did not improve significantly for an extended period in the 1980s and 1990s, indicating a lack of systematic adoption of new fuel efficiency technologies. While the firm with inferior technology capability did push its efficient frontier outward to close the technology gap, the two leading manufacturers’ efficient frontiers first showed signs of regression in the early 1990s, and were not pushed out significantly until the late 1990s. As a result, the industry might have missed an opportunity to reduce the economic and environmental impacts.” This kind of study provides sound arguments for promoting the implementations of governmental fuel efficiency regulations.

The contribution of the transport sector to the climate change problem is often taken in isolation form other economic sectors. O’Donnell et al. (2009) present a case study of a life cycle assessment of the contribution of transport to greenhouse gas emissions in the supply chain of the American wheat grain. An interesting concluding remark is that “... given the contribution of sequestration to the GHG footprint of the supply chain, efforts to green supply chains should consider changes in transportation together with the resultant changes in emissions from production if transportation changes result in changes in production location.”

Along the same lines, Liska and Cassman (2008) make a proposal for standardized life-cycle methods, metrics, and tools to evaluate biofuel systems based on performance of feedstock production and biofuel conversion at regional or national scales, as well as for estimating the net GHG mitigation of an individual biofuel production system to accommodate impending GHG-intensity regulations and GHG emissions trading.

2.2 Analysis and possible gaps in the reported research

Statistical data as well as surveys regarding the evolution of inland transport provide the main sources of information for analyzing the role of inland transport in the climate change problem and the underlying phenomenons that drive it. A vast amount information are available in reports of various national and international institutes and organizations.

A lot of research is currently focusing on developing countries such as China (e.g. Han and Hayashi...
(2008), Creuztig and He (2009), Hu et al. (2009)), where the GHG emissions due to inland transport are growing extremely rapidly and add up to other externalities such as congestion or local air pollution.

Regarding developed countries, we mentioned two papers analyzing the consumers and producers behaviors (Flamm (2009) and Chen and Zhang (2009)). Interestingly, no peer-reviewed study seems to have been published on the impact of the current economic downturn on the reduction of the emissions of the inland transport. This is certainly due to the fact that the relevant statistics are not available yet.

Life-cycle assessment analysis such as in O’Donnell et al. (2009) and Liska and Cassman (2008)) are extremely useful in the analysis of the climate problem because of its inter-sectoral nature. The next section also addresses this issue in the context of electric and hydrogen vehicles, as the energy production issues also need to be adequately considered.

3 Mitigation

3.1 Literature review

Mitigation of climate change effects will involve transformation of the transport sector. New technologies will be used to provide the needed services and also new lifestyles should emerge from the necessity to curb GHG emissions due to transport. In this section we review documents that are dealing with mitigation or abatement actions, including technological options and modal or lifestyle changes.

3.1.1 Technological options

Technology choices to be made in the transport sector in order to achieve substantial abatement of GHG emissions are considered in several publications related to “bottom-up” systems analytic modelling of the energy system. Labriet et al. (2005) describe abatement scenarios obtained with the world MARKAL model which includes a description of 15 interconnected regions. These scenarios show, in particular an evolution toward the following choices of fuels in the different demand sectors, including the transport sector, for the long term:

These authors report similar results obtained with the TIMES integrated assessment model (Labriet and Lonlou (2008)). The advantage of considering the transport sector within a fully fledged worldwide energy system is to relate energy choices in the transport system to some key choices made elsewhere in the energy supply system, like e.g. the development of electricity or hydrogen supply with zero emission.

In the same vein, Krzyzanowski et al. (2008) use a global MARKAL model to assess the possible development of a hydrogen economy in the transport sector. They explore in particular the ways one can establish an efficient support of the transition towards hydrogen based transportation. They argue that Hydrogen based transportation is an environmentally sound alternative to the current, oil-based transportation. Based on their simulations they predict that this transition could take place in the long run. The analysis shows that despite high initial costs, a transition to hydrogen based transportation...
could be feasible in the long run provided a number of concurrent developments take place. In particular, long-term transition would require significant external support, such as governmental aid in form of RD&D support and in learning investments to help the technologies to follow their learning curve and become competitive in the long run...

In Figure 4 we reproduce the simplified description of the transport sector used in the global MARKAL model.

This line of research can also be applied to the analysis of the future of transport in developing countries. Cadena and Haurie (2001) use a MARKAL model to analyse energy and environmental issues for Colombia, studying in particular the clean development mechanism (CDM) projects.

In Figure 5 we reproduce part of the RES of MARKAL-Colombia which indeed encompasses the transport sector.

The same type of analysis can also be performed at a more local level as shown by Caratti et al. (2003) who study the potential of fuel cell cars in an urban environment subject to severe limitations concerning GHG emissions. They use for their study a model called MARKAL-Lite which is a version of the MARKAL model adapted to the representation of energy/technology choices at a city or regional level.

The transport sector is also considered in the computable general equilibrium models that have recently been developed to study the economics of climate change policies. For example Bernard and Vielle (2008) have developed the computable general equilibrium model GEMINI-E3 which contains a description of the transport demand and of the marginal abatement cost curves used to build “top-down” scenarios of the economics of climate change mitigation.

In Figure 6 we reproduce part of the nomenclature of GEMINI-E3 which shows the general economic environment in which the transport sectors are considered.

Interesting results are obtained when one couples a “top-down” CGE model that describes the macroeconomic interactions and a bottom-up “techno-economic” that represents the technology choices in detail and thus permits a better evaluation of the “marginal abatement costs”. Schafer and Jacoby (2006) propose a linked CGE-MARKAL model sys-
tem capable of simulating the macro-level economy and micro-level technology detail of the transport sector. Furthermore, in this approach, a mode choice submodel is used, based on a limited travel time budget of 1.2 hours per person and per day. The issues of calibration of such a hybrid system are delicate to address. In this application the calibration was essentially one-way, from MARKAL to EPPA.

Figure 7: The coupling procedure (Schafer and Jacoby (2006))

In Figure 8 above we reproduce the schematic representation of the coupling method between the “bottom-up” model like MARKAL, “modal split” models and the “top-down” model like EPPA.

There are other detailed energy models permitting an assessment of the evolution of the transport sector under stricter climate policies. Yan and Crookes (2009) analyze the future trends of energy demand and GHG emissions in China’s road transport sector and assess the effectiveness of possible reduction measures. To do that they use the Long-range Energy Alternatives Planning (LEAP) System. They analyze future trends of total energy demand, petroleum (including gasoline, diesel and LPG) demand and GHG emissions in China for a “Business as usual” (BAU) and for a “Best case” (BC) scenario. The analysis shows relative reduction potentials as large as 40.5% for energy use, 46.5% for petroleum use and 39.9% for GHG emissions. We reproduce below one of the figures summarizing these results.

Figure 8: GHG abatement in BC compared with BAU in China and role of each policy measure (Yan and Crookes (2009))

The measures considered are Private vehicle con-

trol (PVC), Fuel economy regulation (FER), Promotion of diesel and gas (PDG), Fuel tax (FT) and Bio-fuel promotion (BFP). They are not including penetration of new carbon free technologies.

Technology assessment can also be performed at a very local level. Haseli et al. (2008) make a comparative assessment in terms of CO2 emissions from a passenger train in Ontario, Canada, using four specific propulsion technologies (i) conventional diesel internal combustion engine (ICE), (ii) electrified train, (iii) hydrogen ICE, and (iv) hydrogen PEM fuel cell (PEMFC) train. The travel under scrutiny is about 60 kilometers long between Oshawa and Toronto.

![Figure 9: Energy consumption (upper graph) and corresponding travel cost (lower graph) of trains with various power train technologies (Haseli et al. (2008)).](image)

It is also interesting to know that according to these authors “... only an electric car based on scenario 1 of electricity production [renewable energy sources including nuclear energy], with [3 or 4 people per car], may be competitive with a modern powertrain ... ”

Lutsey and Sperling (2009) compare transportation greenhouse gas mitigation options with other sectors by constructing greenhouse gas mitigation supply curves of near-term technologies for all the major sectors of the US economy. To do that they use marginal abatement cost curves, also called “GHG mitigation supply curves” that are constructed using a bottom-up approach. The authors do not detail the models that have been used to obtained these marginal cost curves. In their conclusion they claim “... [The] analysis shows that many transportation strategies are cost-effective when compared directly with options in other economic sectors under consistent assumptions. Many transportation efficiency measures generate cost savings over the life of the energy-efficiency equipment investment, when future energy savings are calculated using normal discount factors. [One finds] that such measures within the transportation sector represent half of all of the “no-regrets” options that are available in all the economic sectors...”

A Kaya framework that decomposes greenhouse gas emissions into the product of population, transport intensity, energy intensity, and carbon intensity is used by Yang et al. (2009) to analyze emissions and mitigation options in California to reduce transportation greenhouse gas emissions 80% below 1990 levels by 2050 (called 80in50 scenarios).

They first observe that in California, the transportation sector is the largest contributor of GHG emissions, making up over 40 % of the state’s total in 2006. They also observe that no mitigation option can singlehandedly meet the target goal because travel demand is expected to increase significantly by 2050 and advanced technologies and fuels may not be suitable for use in all subsectors or may be limited in availability. The “silver-bullet” scenarios explore the potential impact of a new “greener” technology and conclude that none of them can achieve the 80in50 goal (see Figure 10 reproduced from the paper).

The Kaya identity is an equation relating factors that determine the level of human impact on climate, in the form of emissions of the greenhouse gas carbon dioxide. It states that total emission level can be expressed as the product of four inputs: population, GDP per capita, energy use per unit of GDP, carbon emissions per unit of energy consumed...
The 80in50 scenarios consist of: The Efficient Biofuels scenario which relies heavily on advanced technologies for biofuels production entirely from cellulosic sources with negligible “land-use change” LUC impacts; the Electric-drive scenario which relies heavily on advanced electric-drive technologies and low-carbon hydrogen and electricity. Limited availability of low-carbon biofuels constrains their use; and the Actor-based scenario which presents a world where, because of much high energy prices, all actors (companies, governments, and individuals) are motivated to reduce energy consumption and GHG emissions, mainly through smaller, more efficient vehicles, reduced per-capita transportation activity, and increased vehicle occupancy load factors.

The authors conclude that “...The 80in50 scenarios illustrate that the 80 % reduction goal could potentially be met in multiple ways. The Efficient Biofuels 80in50 and Electric-drive 80in50 scenarios show that if vehicle and fuels technologies become clean enough, California can preserve its current levels of mobility. The former requires more primary energy and relies heavily on biomass, while the latter uses fuel more efficiently and has the potential for a significantly more diverse resource mix. The Actor-based 80in50 scenario shows that large shifts in social and travel behavior are valuable mitigation options, especially if technology is not as successful. This scenario has the lowest energy resource requirements. ...”

This research can be complemented by the analysis of Sperling and Gordon (2008). In a very detailed survey they examine the possible technological changes in vehicles, in particular for electric and fuel cell cars. They also debate about two fundamental challenges: (a) transforming vehicles to dramatically reduce oil use and greenhouse gas (GHG) emissions and (b) transforming the larger transportation system to expand personal mobility options and reduce their environmental and spatial footprints. Interestingly, they see in the fact that they provide “mobile electricity” the element which may prove most pivotal in determining the success of fuel cell vehicles, thus rejoining Caratti et al. (2003). In their conclusion they claim that “...The challenge of reducing car dependency is especially urgent for China, India, and others in the rapidly expanding economies of the developing world. The car-centric motorization path pioneered by the United States is very costly, not just in terms of energy and environment, but also because of the huge financial and social cost of shoehorning a network of new roads into their already large, dense cities. These developing countries need to find a new path. That new path is unlikely to be characterized by leapfrog technologies...”

Considering a problem which is particular to Taiwan, Liao et al. (2009) examine carbon dioxide emissions of truck-only inland transport and compare those with intermodal coastal shipping and truck movements. They use an activity-based emission modelling approach. “...This study has illustrated
possible positive changes in CO2 emissions if intermodal of coastal shipping and truck is adopted in the place of truck-only transport for export/import container movements in Taiwan. The reductions in CO2 emissions is mainly driven by the efficiency of maritime fuel (heavy oil and diesel) use compared to the diesel used by trucks..."

In a case study concerning Australia Stanley et al. (2009) investigate two targets for road transport greenhouse gas emissions, in 2020 and 2050 respectively and what they might mean for the sector.

For the 2020 target (20 % below 2000 emission levels) the paper suggests the following six key ways to attain it: (1) Reduce urban car kilometres travelled. (2) Increase the share of urban trips performed by walking and cycling. (3) Increase public transport’s mode share of urban motorized trips. (4) Increase urban car occupancy rates. (5) Reduce forecast fuel use for road freight. (6) Improve vehicle efficiency.

For the 2050 target (80 % below 2000 levels) the authors claim that the only way to make it compatible is in significantly changing travel behaviour to increase the role of low carbon modes and/or, low-ering the emission reduction target for the transport sector, which increases the burden to be taken up by other sectors.

Finally let us mention the multi-criteria analysis made by Granovskii et al. (2006)] who compare conventional, hybrid, electric and hydrogen fuel cell vehicles using both economic and environmental indicators. The method produces a technology ranking.

3.1.2 Lifestyle Changes

The domain of research consisting of evaluating lifestyle changes leading to sustainable transport is much less developed than the technological options one.

In a paper related to the one of Yang et al. (2009), McCollum and Yang (2009) investigate the potential for making deep cuts in US transportation greenhouse gas (GHG) emissions in the long-term (50–80% below 1990 levels by 2050). Scenarios are used to envision how such a significant decarbonization might be achieved through the application of advanced vehicle technologies and fuels, and various options for behavioral change. They concludes that “...[the scenarios] confirm results from other studies, showing that no one mitigation option can single handedly meet the ambitious GHG goals, especially since total travel demand in each subsector is expected to increase significantly by 2050. This puts a large burden on vehicle and fuel technologies to decarbonize, and by our estimates it is unreasonable to think a single technology approach can shoulder this burden entirely on its own, given the diversity of vehicle types and requirements in the transportation sector.”

Grazi et al. (2008) analyze whether urban form affect travel choices, by decomposing travel demand into components related to modal split and commuting distance by each mode. “...All taken together, urban form, and therefore policies that affect urban form, such as spatial and transport planning, deserve more attention in climate policy debates, as they can contribute to a reduction in greenhouse gases. For example, transport planning may try to stimulate modal shift by increasing density through the development of new public transport, such as the planned additional subway line in the centre of Amsterdam, and thus allow the design of a more effective transport infrastructure network as well as the creation of fast lanes for buses and separate lanes for bicyclists....”

Caulfield (2009) examines the patterns of ride-sharing, in Dublin, and estimates the environmental benefits of ride-sharing both in terms of reductions in emissions and the vehicle kilometers traveled.

Wright and Fulton (2005) employs scenario analysis to examine the size and cost of potential emission reduction options from the urban transport sector of developing nations. In particular, the analysis compares the cost of greenhouse gas emission reductions from fuel technology options to reductions from measures promoting mode shifting. This comparative analysis indicates that a diversified package of measures with an emphasis on mode shifting is likely to be the most cost-effective means to greenhouse gas emission reductions.
3.2 Analysis and possible gaps in reported research

The analysis of technological options to mitigate climate change due to transport is tackled mostly through the use of bottom-up models. LEAP, MARKAL or TIMES models have been used to represent technology and energy choices for transport in relation with the evolution of the whole energy supply system (Labriet et al. (2005), Caratti et al. (2003), Krzyzanowski et al. (2008), Cadena and Haurie (2001)). A top-down approach, based on the use of computable general equilibrium models can also be coupled with the bottom-up analysis performed by MARKAL like models (Schafer and Jacoby (2006)). The linking concept between bottom-up and top-down models is the “marginal abatement cost” curve which can be constructed using an integrated energy supply model like MARKAL or more transport sector specific model (Lutsey and Sperling (2009), Yan and Crookes (2009)). The other papers in this section analyse specific technological options (Granovskii et al. (2006), Liao et al. (2009), or country/region specific options (Stanley et al. (2009), Yan and Crookes (2009), Yang et al. (2009)). One paper (Sperling and Gordon (2008)) examines the larger debate of improving current technologies vs. transforming the transport system.

Our perception of the possible gaps in research is that the recent development of better top-down and bottom-up description of the world economy and of the world energy system, including a more precise description of emerging economies (BRIC), as well as the progresses in coupling methods to link BU and TD models, should be exploited to generate scenarios for the implementation of sustainable transport systems in emerging and developing countries. A similar analysis could also be undertaken for EU, considering the availability of CGE (GEMINI-E3, Bernard and Vielle (2008)) and technology rich (TIMES Labriet and Loulou (2008)) models well calibrated for this region of the world.

There is a need for the development of quantitative models, like LEAP, MARKAL, TIMES or GEMINI-E3 which would include actions oriented toward the modification of the demand pattern for energy or transport services. A modeling effort should be undertaken to generalize and to incorporate in a “bottom-up” approach the trade-off between technology and system-wide improvements in the transport sector as proposed by Sperling and Gordon (2008). In particular the need for an active governmental support to invest in the needed infrastructure to permit a development of electric or fuel cell cars should be further studied.

4 Vulnerability and adaptation issues

4.1 Literature review

The increasing evidence that climate change is happening seems to have triggered an increased interest in the other side of the medal, i.e. the impact of climate change on transport and the potential ways of adaptation. Events such as hurricane Katrina, have demonstrated the vulnerability of our societies, including our transportation systems, to climate variations. In the extensive report on the US Gulf Coast Study on the Impacts of Climate Change and Variability on Transportation Systems and Infrastructure, Savonis et al. (2008) deal with impacts of Katrina on transport infrastructure, and especially on pipelines. They underline that “At the peak of the disruption caused by Hurricane Katrina, [...] all major pipelines in the area were inoperable due to power outages. By September 4, 5 days after the storm, [...] all of the major crude or petroleum product pipelines had resumed operation at either full or near-full capacity”. In their conclusions, they stress the implications of climate change for transport planning, i.e. longer planning timeframes, connectivity of the intermodal system and teh need for integrated analysis. Finally, they list Climate Data and Projections, Risk Analysis Tools, Region-Based Analysis and Interdisciplinary Research as the major requirements for and adequate assessment of the of the impacts of a changing climate on transportation infrastructure and services.

Another detailed report (National Research Council (2008)) describes the potential impacts of climate change on the whole U.S. Transportation. It presents the major impacts of climate change on transport
infrastructure and operations, as reproduced in table refnat. It finally concludes by presenting 14 recommendations for future transport planning, such as extending the planning horizon beyond the standard 20-30 years thus allowing one to take climate change into adequate consideration.

The transportation chapter in Lemmen and Warren (2004) also provides an overview of research in the field of climate change impacts and adaptation focusing on Canada. They stress that “it is to be expected that many gaps exist in our understanding of potential climate change impacts and adaptation strategies in the transportation sector. Given the limited amount of work that has been completed, virtually all impact areas and adaptation strategies require further investigation. Specific priorities identified within papers cited in this chapter include:

- greater attention to impacts and adaptation issues for road transportation in southern Canada;
- increased research on the vulnerability of Canadian roads to changes in thermal conditions, including freeze-thaw cycles and extreme temperatures;
- studies that assess the significance of extreme weather events and weather variability in the design, cost, mobility and safety of Canadian transportation systems;
- a more thorough evaluation of existing adaptive measures and their relative ability to defer infrastructure upgrades, reduce operational costs, and maintain or improve mobility and safety;
- comprehensive studies that focus on key issues for shipping and navigation, including the opening of the Northwest Passage and lower water levels in the Great Lakes-St. Lawrence Seaway system;
- an analysis of how changes in factors external to climate, such as technology, land-use patterns and economics, affect societal vulnerability to climate and climate change; and
- studies that integrate mitigation (greenhouse gas emissions reduction) and climate change-related impacts and/or adaptation issues.”

In their survey of the empirical literature on the effects of climate change and weather conditions on the transport sector, Koetze and Rietveld (2009) also stress that far less literature has been published on the impacts of and adaptation to climate change than on mitigation. They summarize part of their finding as follows. “On a global scale especially the increase in temperatures may influence patterns in tourism and skiing holidays, with the associated changes in passenger transport. We may also expect global shifts in agricultural production, with associated changes in freight transport. The predicted rise in sea levels and the associated increase in frequency and intensity of storm surges and flooding incidences may furthermore be some of the most worrying consequences of climate change, especially for coastal areas. Empirical research for Europe is limited, but research for the US East Coast and Gulf area shows that the effects on transport and transport infrastructure may be substantial. However, because flood-defenses that are already in place are included in none of the studies, the insights may have limited value for assessing future flood-risk and exposure for specific locations, and likely also overestimate total exposure and damages due to climate change. Climate change related shifts in weather patterns might also affect infrastructure disruptions. For road transport most studies focus on traffic safety and congestion. With respect to traffic safety by far the most important variable is precipitation, most studies finding that precipitation increases accident frequency, but decreases accident severity. The mediating effect in here is likely that precipitation reduces traffic speed, thereby reducing the severity of an accident when it occurs. Furthermore, most studies show a reduction in traffic speed due to precipitation and especially snow. Interestingly, the effect is particularly large during peak hours and on congested roads. The few existing insights for rail transport show that high temperatures, icing, and strong winds, among others, may cause considerable delays. For the aviation sector, wind speeds, wind direction and visibility have clear effects on safety and delays and cancelations. This has large cost implications, both for airlines and travelers. However, implications of climate change on wind speeds but especially on wind directions and developments with respect to mist, fog and visibility are highly uncertain. Finally, changes in temperature and precipitation have consequences for riverine water levels. Low water levels will force inland waterway vessels to use

</table>
only part of their maximum capacity, which may con-
siderably increase transportation costs in the future.”

More specifically, Jonkeren et al. (2009) assess the
effect of low water levels on the costs of transport op-
erations and modal split for inland waterway trans-
port in North West Europe under several climate sce-
narios. They find that “climate change is likely to
affect inland waterway transport prices via low water
levels which may lead to a deterioriation of the com-
petitive position of inland waterway transport com-
pared to rail and road transport. We studied this
issue using NODUS, a GIS-based strategic freight
network planning model that combines supply, de-
mand and cost functions to assign flows on a multi-
modal network. At first, a base scenario was created
describing a fictitious year with average daily water
levels, as modelled from 1986 to 1995. The alterna-
tive scenarios were based on several climate scenarios
which implied increases in the costs for inland wa-
terway transport due to low water levels. Relative to
the base scenario, we estimated a reduction in the an-
ual quantity transported by barge of about 2.3 % in
the case of KNMI’06 climate scenario M+, and about
5.4 % in the case of scenario W+, in the Kaub-related
Rhine market.13 As a result, the volume of road ve-
hicle kilometres and the volume of CO$_2$ emission in-
crease with about 1 %.”

If inland waterways are very likely to be affected,
other modes of transport are also at stake. Lind-
gren et al. (2009) summarize a case study on the fu-
ture vulnerability to climate change of the Swedish
railway transport system and its adaptive capacity.
They also make a recent and complete literature re-
view at the crossroad of adaptation and transporta-
tion. They conclude that “without doubt, it will be
a challenge for the railway sector to cope with fu-
ture climate change, and its adaptive capacity will
be thoroughly tested during the coming decades. The
results from this case study highlight several climate-
related threats that could have severe negative con-
sequences for the railway system. The most im-
portant of these relate to high water levels, both in
streams and groundwater, high wind speeds and rapid
changes in temperature. All of these are potential
consequences of climate change. A positive aspect
of climate change that may reduce the vulnerability,
especially for Northern Europe, relates to milder con-
ditions in winter. ”

In chapter 4.3 of Savonis et al. (2008) we find some
case studies of adaptation of transport infrastruc-
ture to climate changes, for instance adaptation to
sea level rise by elevation of an highway. They pro-
vide the example of Louisiana Highway 1, which is in
process of getting some of its portions elevated, and
stress the importance of hurricane Katrina in raising
the awareness of vulnerability.

Climate change is also very likely to have significant
impacts on urban transportation systems of costal
cities. Suarez et al. (2005) study the impacts of flood-
ing and climate change on urban transportation in
the the Boston Metro Area. They conclude that “...the
Boston Metro Area is already heavily built and
therefore will not be much change in urban infra-
structure compared to other metropolitan areas in
the US and worldwide. The transportation network
has great redundancy and therefore it is not too vul-
nerable to extreme events from a system wide per-
spective. Consequently, there is little margin of ac-
tion in terms of modifying the existing infrastructure
based on the results of this modeling effort. How-
ever, for urban areas experiencing more rapid land
use conversion, or located in more hazard- prone ar-
eas, the methodology presented in this work can prove
very useful for exploring choices in terms of how to
guide urban growth and how to develop an integrated
plan for managing transportation systems facing the
threat of increased flooding.”

More globally, Jaroszweski et al. (2009) empha-
size the need to utilize an interdisciplinary approach
to Climate Change Impact Assessment (CIA) taking
into account both climate and socioeconomic scenar-
ios. They emphasize that “... the nature of future
society cannot be predicted. However it is possible to
present a range of plausible scenarios that may hap-
pen. It is this concept of scenarios which is key to
developing a useful CIA. Depending on the dominant
socio-economic drivers present over the coming cen-
tury, the transport network of the future may be more
or less vulnerable to the impacts of meteorological
events. It will both drive the type of infrastructural
projects which are commenced during this period and
influence the way in which they are used. By provid-
ing a range of scenarios it is possible for governments,
organisations and companies to have a greater insight
into the ‘futures’ into which their investments will be
placed.”
Institution of Mechanical Engineers (2008) examines climate change predictions, using the GENIE-1 model (http://www.genie.ac.uk/), for three geographical regions (UK, Shanghai in China and Botswana), chosen for their differing maritime, monsoonal and continental climates, and different stages of economic development. The Institution of Mechanical Engineers has a strong belief that “... unless we adapt, we are likely to face a difficult future.” It also views adaptation as the next challenge for engineer and state that “... all current modes of transport will still be in use in 100-200 years’ time, albeit in modified forms. Much of the built infrastructure will need to be assessed for vulnerability and resilience to climate change. Master planning will need to consider alternative routes and extra capacity as well as build in redundancy, particularly in the case of rail where much of the infrastructure is sited on flood plains and coastal fringes.”

4.2 Analysis and possible gaps in the reported research

The climate changes that could have a direct impact on transport infrastructure are sea level rise (oceans), low water levels (rivers), storm surge and flooding (Koetze and Rietveld (2009)). Impacts on transport demands (freight, agriculture, passenger) are more difficult to assess but the possible availability of a northern sea route or a northwest passage might have significant consequences on international freight transportation.

The question of evaluating climate impact on transportation is a key point (Jaroszweski et al. (2009)) and needs a global approach to be answered. It could be interesting to develop this field of research, probably by a global modeling approach.

Several researches have been carried out in the U.S (National Research Council (2008), Savonil et al. (2008), Suarez et al. (2005)), Canada (Lemmen and Warren (2004)) and Europe (Jonkeren et al. (2009)), with some focusing particularly on flooding and sea level rise impacts. There are still few researches on adaptation in developing countries and papers such as Molua (2009) do not deal with climate change impacts on transportation. Therefore, research could be extended to developing countries and more specifically in Middle East, North Africa and East Asia, regions known to be highly vulnerable.

So far, it remains very difficult to assess adaptation policies (Lemmen and Warren (2004), Lindgren et al. (2009)). Today, most adaptation measures are still taken as a response to current climate variability. The major question governments are facing is is how to include long term climate change in the transport systems strategy and planning. Finally, it would also be interesting to evaluate current adaptation projects.
